Models of manufacturing systems

Performance measures:

- Throughput δ
- Flow time φ
- Work-in-process w

Shopfloor realities:

- Machine downs, repairs, setup, product mix, operators, batching, product recipes, priority lots, ...

Modeling approaches:

- Queueing (network) analysis (exact/approximation)
- Discrete-event simulation

Application

Models of manufacturing systems

Queueing (network) analysis (exact/approximation):

- Computationally efficient: ideal for what-if and optimization studies
- Limited applicability due to restrictive assumptions regarding shopfloor realities

Discrete-event simulation:

- Shopfloor realities may be modeled in detail
- Computationally intensive

Model parameters:

- Can we obtain all required data to set the model parameters?

Introduction

EPT concept

Research project

Progress

Application

Example: a production flow line

Flowline characteristics:

- Infinite buffers, single-server stations, single-lot machines.

Shopfloor realities:

- Process mix, setup-times, recipes, operator availability, machine downs, repair, rework, hot-lots, sequencing, scheduling, shopfloor control, ...

Contents

Introduction

EPT concept

Research project

Progress

Application

Zooming in: single-server workstation

Reality:

Natural processing

Random failures (preemptive): e.g. machine downs

Planned process delays (non-preemptive): e.g. setups

Aggregation:

Effective process time

(EPT parameters t_e and c_e^2 may be estimated

by adding natural processing and preemptive

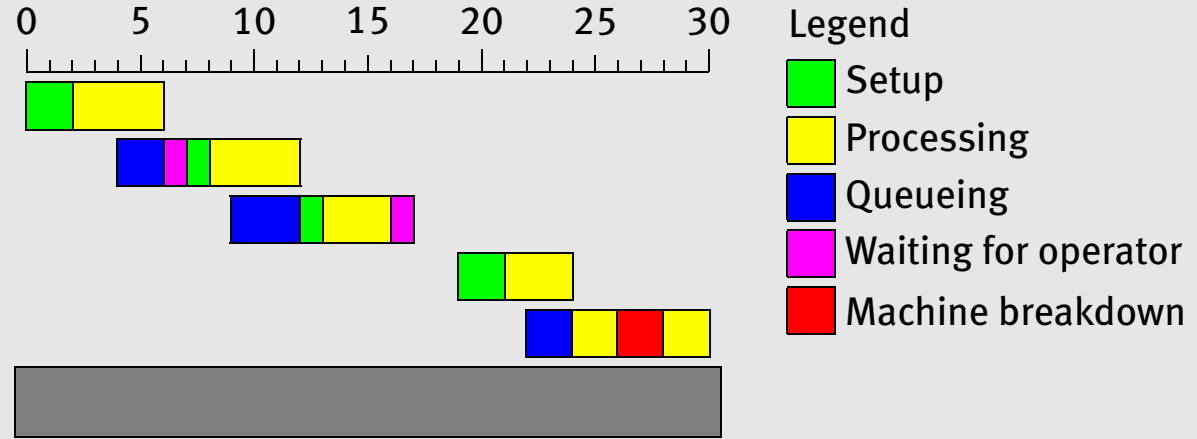

and nonpreemptive outages)

Queueing model: $CT = \frac{c_a^2 + c_e^2}{2} \frac{u}{1-u} t_e + t_e, \quad u = \frac{t_e}{t_a}$

[Hopp, Spearman, 2000]

Application

Research objective and approach

Goal:

- To build simple yet accurate models of manufacturing networks using operational factory data *without* the need to characterize all contributing disturbances and shopfloor realities.

Approach:

- Effective process time paradigm in aggregate modeling and parameter identification
- Efficient queueing network approximations through iterative algorithms based on decomposition

[Contents](#)[Introduction](#)[EPT concept](#)[Research project](#)[Progress](#)[Application](#)

Challenges

Machine:

- Single-lot, batching, conveyor, assembly, other types, ...

Workstation (multiple parallel servers sharing a buffer):

- Dispatching, recipes, unequal machines, lot overtaking, ...

Network:

- Blocking (finite buffers), assembly lines, re-entrant flow lines, general queueing network, production control, ...
