# $\mathrm{AVS}/\mathrm{R}$ System Overview

- AVS/RS: Uses autonomous vehicles instead of aisle-captive cranes
- System configuration
  - Rectilinear movement
  - Horizontal movement (x and y axes) by autonomous vehicles
  - Vertical movement (z axis) by lifts
  - Vehicles move between tiers using lifts
- Modular and adaptive design

・ロト ・ 日 ・ ・ ヨ ・ ・ 日 ・

# Components of an AVS/R System

æ

# Design Parameters in AVS/RS

#### System Sizing Decisions

- Number of vehicles and lifts
- Depth/Width ratio
- Location of cross-aisle and load/unload points
- Number of zones

#### **Operational Decisions**

- Vehicle assignment rule
- Dwell point policy
- Command cycle
- Storage policy
- Transaction scheduling policy (FCFS, Random)

#### Key Performance Measures

• Transaction cycle time, Queue lengths, Throughput, Vehicle utilization

### Outline

# Review of Analytical Models for AVS/RS

Author	Method	
Malmborg $(2002, 2003)$	State equation based models	
Kuo et al. (2004)	Probabilistic approach	
Zhang et al. $(2008)$	Variance based approximations	
Heragu and Srinivasan (2008)	Semi-open queuing networks	
Roy et al. (2009)	Semi-open queuing networks	

#### Objective of these models

- Model vehicle-lift interface and its effect on cycle times
- Quantify performance benefits of AVS/R systems

Limitation: These models does not account for possible vehicle interference and its effect on system performance

Focus of Current Research

# Types of Vehicle Interference

æ

# Current Research: Analyze the Effect of Vehicle Interference

- Is the effect of vehicle interference significant?
- Efficient single tier systems form effective building blocks for multi-tier systems

・ロト ・ 同ト ・ ヨト ・ ヨト

# Research Approach

- Develop protocols for vehicle interference
- Develop a semi-open queuing network model of a single tier
- Solve the model using a decomposition based approach
- Validate the analytical model against simulations
- Analyze the effect of vehicle interference on performance

・ロト ・四ト ・ヨト ・ヨト

# Protocols for Vehicle Interference

Each half of the cross-aisle has at most one vehicle at any time t:

Vehicles within an aisle yield to other incoming vehicles:

#### Queuing Model

# Assumptions

- System Design Assumptions
  - $\bullet~ {\rm One~load}/{\rm unload~point}$
  - Single command cycle
  - Random vehicle assignment
  - LU dwell point policy
  - Random storage policy
  - FCFS transaction scheduling

• Model Assumptions

• Poisson arrivals

# Description of Vehicle Classes

Vehicle Class Prior to	Transaction	Vehicle Class After
Start of Service	Type	Start of Service
Store $(s)$	Retrieval	Retrieve $(r)$
Store $(s)$	Storage	Store $(s)$
Retrieve $(r)$	Retrieval	Retrieve $(r)$
Retrieve $(r)$	Storage	Store $(s)$

# Queuing Model for a Single Tier: Decomposition

Vehicle Interference Effects

# Decomposition Based Approach for Solving the Model

- For case  $(y \leq 0)$ : Solve the closed queuing network with two classes of vehicles: Store (s), and Retrieve (r) using an Approximate MVA (AMVA) algorithm
- 2 For case  $(y \ge 0)$ : Solve the open queue as an M/G/1 queue
- <sup>3</sup> Link results from the above two cases and obtain the steady state distribution of the vehicles and transactions in the original semi-open queuing network
- Obtain the performance measures (cycle time, vehicle distribution in the network and vehicle utilization)

イロン 不同 とくさい 不良 とうせい

# CQN for case $(y \le 0)$

æ

# Solution for case $(y \leq 0)$

Node Characteristics:

- Aisle nodes  $(Q_1, \ldots, Q_N)$ : LCFS-PR with exponential service times  $(\mu_{A_1} = \mu_{A_2} = \ldots = \mu_{A_N})$ , where N is the number of aisles
- Cross-aisle nodes  $(Q_{N+1} \text{ and } Q_{N+2})$ : FCFS with uniform service times  $(\mu_{CA_L} = \mu_{CA_R} \text{ and CV of } 0.58)$
- LU nodes  $(Q_{N+3})$ : IS with exponential service times
- Wait for transaction node  $(Q_{N+4})$ : FCFS node with exponential service time

Therefore, the network is non-product form (Baskett et al. (1975)) and an Approximate MVA algorithm (Lazowska et al. (1984)) is used to obtain conditional measures.

# Solution for case $(y \ge 0)$

• When y > 0, arriving transactions wait for a vehicle

- Approach
  - Solve as an open queue with a single server station
- Challenges
  - Determine  $\mu_T^{-1}$  (average service time) and coefficient of variation (CV) of the service time

3

・ロト ・回ト ・ヨト ・ヨト

# Determining $\mu_T$ for case $(y \ge 0)$

# Solution for case $(y \ge 0)$

- CV of service time:
  - From simulation studies, the CV of the service time is 0.6-0.8
  - We estimate the CV by analyzing the vehicle distribution in a reduced closed queuing network
- Solution of open queue:
  - $\bullet\,$  Open queue is analyzed as an M/G/1 queue
  - Determine  $\pi(i|y\geq 0)$  by analyzing an M/G/1 queue with service rate  $\mu_T$

# Unconditional Probabilities

• For Case 1 
$$(y \le 0)$$
:

 $\pi(y=i) = \sum_{q:|Q_{N+4}|=-i} \pi_q(|Q_1|, |Q_2|, \dots, |Q_{N+4}||y \le 0) \pi(y \le 0)$  $\forall i = 0, \dots, -V \text{ where } |Q_m| \text{ denote the number of vehicles at node } m$ 

• For Case 2 
$$(y \ge 0)$$
:

$$\pi(y=i) = \pi(i|y \ge 0)\pi(y \ge 0) \forall i = 0, .., \infty$$

Two unknowns  $\pi(y \ge 0)$  and  $\pi(y \le 0)$ 

•  $\pi(y=0)$  is common to both cases

**2** 
$$\sum_{k=-V}^{\infty} \pi(y=k) = 1$$

・ロト ・日 ・ ・ ヨ ・ ・ ヨ ・ うへの

## Performance Measures

- Using  $\pi(y=i)$ , we can obtain the following performance measures:
  - Vehicle utilization
  - Average number of transactions waiting for service
  - Expected storage cycle time and retrieval cycle time

# Model Validation against Simulation

- Design Parameters
  - Vehicles = 3.5
  - $\frac{D}{W} = 0.5, 1.5$
  - $\lambda_s + \lambda_r = 45 100 \ pall./hr$  in increments of 5 pall./hr
  - Number of storage locations=7300
- Analyzed 40 cases where vehicle utilizations range between 60% to 90%
- Simulation: Modeled using AUTOMOD path mover system (15 replications for each scenario, 96000 transactions per run)

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・

## Model Validation:Results

 $\% Error = \frac{A-S}{S}$ , where S=Simulation Value and A=Analytical Value

æ

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・

Effect of Vehicle Interference on Cycle Times:  $\frac{D}{W} = 1.5$ 

#### Tier Configuration: 7300 Locations, 45 Aisles, 81 Columns, 5 Vehicles

æ

・ロト ・ 同ト ・ ヨト ・ ヨト

Effect of Vehicle Interference on Cycle Times:  $\frac{D}{W} = 0.5$ 

Tier Configuration: 7300 Locations, 27 Aisles, 135 Columns, 5 Vehicles

3

### Summary and Next Steps

Conclusions:

- Developed analytical model of single tier with vehicle interference
- Vehicle interference increase cycle times

Next Steps:

- Refine analytical model and validate against detailed simulations
- Use analytical model to obtain design insights
- Model to account for lift interactions in multi-tier systems
