#### Abstract

We consider estimation of the emission parameters in hidden Markov models. Commonly, one uses the EM algorithm for this purpose. However, our primary motivation is the Philips speech recognition system wherein the EM algorithm is replaced by the Viterbi training algorithm. Viterbi training is faster and computationally less involved than EM, but it is also biased and need not even be consistent. For this reason we propose an alternative to the Viterbi training - adjusted Viterbi training - that has the same order of computational complexity as Viterbi training but gives more accurate estimators. Elsewhere, we studied the adjusted Viterbi training for a special case of mixtures with relevant simulations ascertaining the theory. This paper shows how the adjusted Viterbi training is also possible for more general hidden Markov models.

[^0]
## 1 Introduction

We consider a set of procedures to estimate the emission parameters of a finite state hidden Markov model given observations $x_{1}, \ldots, x_{n}$. Thus, $Y$ is a Markov chain with (finite) state space $S$, transition matrix $\left(P_{i j}\right)$, and initial distribution $\pi$. To every state $l \in S$ there corresponds an emission distribution $P_{l}$ with density $f_{l}$ that is known up to the parametrization $f_{l}\left(x ; \theta_{l}\right)$. When $Y$ reaches state $l$, an observation according to $P_{l}$ and independent of everything else, is emitted.

The standard method for finding the maximum likelihood estimator of the emission parameters $\theta_{l}$ is the EM-algorithm that in the present context is also known as the Baum-Welch or forward-backward algorithm [1, 2, 7, 8, 15, 16]. Since the EM-algorithm can in practice be slow and computationally expensive, one seeks reasonable alternatives. One such alternative is Viterbi training (VT). VT is used in speech recognition [7, 12, 16, 17, 18, 19], natural language modeling [13], image analysis [11], bioinformatics [4, 14]. We are also motivated by connections with constrained vector quantization [3, 5]. The basic idea behind VT is to replace the computationally costly expectation (E) step of the EM-algorithm by an appropriate maximization step with fewer and simpler computations. In speech recognition, essentially the same training procedure was already described by L. Rabiner et al. in [9, 17] (see also [15, 16]). Rabiner considered this procedure as a variation of the Lloyd algorithm used in vector quantization, referring to Viterbi training as the segmential $K$-means training. The analogy with the vector quantization is especially pronounced when the underlying chain is simply a sequence of i.i.d. variables, observations on which are consequently an i.i.d. sample from a mixture distribution. For such mixture models, VT was also described by R. Gray et al. in [3], where the training algorithm was considered in the vector quantization context under the name of entropy constrained vector quantization (ECVQ).

The VT algorithm for estimation of the emission parameters of the hidden Markov model can be described as follows. Using some initial values for the parameters, find a realization of $Y$ that maximizes the likelihood of the given observations. Such an $n$-tuple of states is called a Viterbi alignment. Every Viterbi alignment partitions the sample into subsamples corresponding to the states appearing in the alignment. A subsample corresponding to state $l$ is regarded as an i.i.d. sample from $P_{l}$ and is used to find $\hat{\mu}_{l}$, the maximum likelihood estimate of $\theta_{l}$. These estimates are then used to find an alignment in the next step of the training, and so on. It can be shown that in general this procedure converges in finitely many steps; also, it is usually much faster than the EM-algorithm.

Although VT is computationally feasible and converges fast, it has a significant disadvantage: The obtained estimators need not be (local) maximum likelihood estimators; moreover, they are generally biased and inconsistent. (VT does not necessarily increase the likelihood, it is, however, an ascent algorithm maximizing a certain other objective function.) Despite this deficiency, speech recognition experiments do not show any significant degradation of the recognition performance when the EM algorithm is replaced by VT. There appears no other explanation of this phenomena but the "curse of complexity"
of the very speech recognition system based on HMM.
This paper considers VT largely outside the speech recognition context. We regard the VT procedure merely as a parameter estimation method, and we address the following question: Is it possible to adjust VT in such a way that the adjusted training still has the attractive properties of VT (fast convergence and computational feasibility) and that the estimators are, at the same time, "more accurate" than those of the baseline procedure? In particular, we focus on a special property of the EM algorithm that VT lacks. This property ensures that the true parameters are asymptotically a fixed point of the algorithm. In other words, for a sufficiently large sample, the EM algorithm "recognizes" the true parameters and does not change them much. VT does not have this property; even when the initial parameters are correct (and $n$ is arbitrarily large), an iteration of the training procedure would in general disturb them. We thus attempt to modify VT in order to make the true parameters an asymptotic fixed point of the resulting algorithm. In accomplishing this task it is crucial to understand the asymptotic behavior of $P_{l}^{n}$, the empirical measures corresponding to the subsamples obtained from the alignment. These measures depend on the set of parameters used by the alignment, and in order for the true parameters to be asymptotically fixed by (adjusted) VT, the following must hold: If $P_{l}^{n}$ is obtained by the alignment with the true parameters, and $n$ is sufficiently large, then $\hat{\mu}_{l}$, the estimator obtained from $P_{l}^{n}$, must be close to the true parameters. The latter would hold if

$$
\begin{equation*}
P_{l}^{n} \Rightarrow P_{l}, \quad \text { a.s. } \tag{1}
\end{equation*}
$$

and if the estimators $\hat{\mu}_{l}$ were continuous ${ }^{1}$ at $P_{l}$ with respect to the convergence in (1). The reason why VT does not enjoy the desired fixed point property is, however, different and is that (1) need not in generally hold. Hence, in order to improve VT in the aforementioned sense, one needs to study the asymptotics of the measures $P_{l}^{n}$. First of all, one needs to know if there exists any limiting probability measures $Q_{l}$ such that for every $l \in S$

$$
\begin{equation*}
P_{l}^{n} \Rightarrow Q_{l}, \quad l \in S \quad \text { a.s.. } \tag{2}
\end{equation*}
$$

If such limiting measures exist, then under the above continuity assumption, the estimators $\hat{\mu}_{l}$ will converge to $\mu_{l}$, where

$$
\mu_{l}=\arg \max _{\theta_{l}} \int \ln f_{l}\left(\theta_{l}, x\right) Q_{l}(d x)
$$

Taking now into account the difference between $\mu_{l}$ and the true parameter, the appropriate adjustment of VT, so called adjusted Viterbi training (VA) can be defined (§2.2).

Let us briefly introduce the main ideas of the paper. Let $X$ stand for the observable subprocess of our HMM. The core of the problem is that the alignment is not defined for infinite sequences of observations, hence the asymptotic behavior of $P_{l}^{n}$ is not straightforward. To handle this, we introduce the notion of barrier (§3). Roughly, a barrier is a block of observations from a predefined cylinder set that has the following property: Alignments for contiguous subsequences of observations enclosed by barriers can be

[^1]performed independently of the observations outside these enclosing barriers. A simple example of a barrier is an observation $z$ that determines, or indicates, the underlying state: $x_{u}=z \Rightarrow y_{u}=l, u \leq n$. This happens if $z$ can only be emitted from $l$. This also implies that any Viterbi alignment has to pass through $l$ at time $u$, and in particular, the alignment up to $u$ does not depend on the observations after time $u$. If a realization had many such special $z$ 's, then the alignment could be obtained piecewise, gluing together subalignments each for each segment enclosed by two consequitive $z$ 's.

Barriers are a generalization of this concept. A barrier is characterized by containing a special observation termed a node (of order $r \geq 0$ ). Suppose a barrier is observed with $x_{u}$ being its node. Now, the definition of the node guarantees the existence of state $l$ such that any alignment passes through $l$ at time $u$ independently of the observations outside the barrier.

In Lemma 3.1, we prove (under certain assumptions) the existence of a special subsequence, or a block, of $Y$ states such first, the subsequence itself occurs with a positive probability, and second, with a positive probability, it emmits a barrier. Hence, by ergodicity of the full HMM process, almost every sequence of observations has infinitely many barriers emitted from this special block. Next, we introduce random times $\tau_{i}$ 's at which such nodes are emitted. Note that $\tau_{i}$ 's are unobservable: We do observe the barriers but without knowing whether or not the underlying MC is passing throught that special block at the same time. It is, However, not difficult to see that the times $T_{i}=\tau_{i}-\tau_{i-1}$ are renewal times, and furthemore, the process $X$ is regenerative with respect to the times $\tau_{i}$ (Proposition 4.2).

Recall that almost every sequence of observations has infinitely many barriers and that every barrier contains a node. For a generic such sequence, let $u_{i}$ be the times of its nodes. Note that $u_{i}$-s are observable and that also every for all $j=1,2, \ldots, \tau_{j}=u_{i}$ for some $i \geq j$ (there may be more nodes than those emitted from the special block). Using these $u_{i}$ 's as dividors, we define infinite alignment piecewise (Definition 4.1). Formally we have defined a mapping $v: \mathcal{X}^{\infty} \rightarrow S^{\infty}$, where $\mathcal{X}^{\infty}$ is the set of all possible observation sequences, and $S^{\infty}$ is the set of all possible state-sequences. Hence, $V=v(X)$ is a well defined alignment process. We consider the two-dimensional process $Z:=(X, V)$, and we note that this process is also regenerative with respect to $\tau_{i}{ }^{\prime}$ s. We now define empirical measures $Q_{l}^{n}$ that are based on the first $n$ elements of $Z$ (Definition 4.2). Using the regenerativity, it is not hard to show that there exists a limit measure $Q_{l}$ such that $Q_{l}^{n} \Rightarrow Q_{l}$, a.s and $P_{l}^{n} \Rightarrow Q_{l}$ (Theorem 4.4). This is the main result of the paper.

To implement VA in practice, a closed form of $Q_{l}$ (or $\hat{\mu}_{l}$ ) as a function of the true parameters is necessary. The measures $Q_{l}$ depend on both the transition and the emission parameters, and computing $Q_{l}$ can be very difficult. However, in the special case of mixture models, the measures $Q_{l}$ are easier to find. In [10], VA is described for the mixture case. The simulations in [10] verify that VA indeed recovers the asymptotic fixed point property. Also, since the appropriate adjustment function does not depend on the data,
each iteration of VA enjoys the same order of computational complexity (in terms of the sample size) as the baseline VT. Moreover, for commonly used mixtures, such as, for example mixtures of multivariate normal distributions with unknown means and known covariances, the adjustment function is available in a closed form requiring integration with the mixture densities. Depending on the dimension of the emission, the number of components, and on the available computational resources, one can vary the accuracy of the adjustment. We reiterate that, unlike the computations of the EM algorithm, computations of our adjustment do not involve evaluation and subsequent summation of the mixture density at every data point. Also, instead of calculating the measures $Q_{l}$ exactly, one can easily simulate them producing in effect a stochastic version of VA. Although simulations do require extra computations, the overall complexity of the stochastically adjusted VT can still be considerably lower than that of EM, but this, of course, requires further investigation.

## 2 Adjusted Viterbi training

In this section, we define the adjusted Viterbi training and we state the main question of the paper. We begin with the formal definition of the model.

### 2.1 The model

Let $Y$ be a Markov chain with finite state space $S=\{1, \ldots, K\}$. We assume that $Y$ is irreducible and aperiodic with transition matrix $P=\left(p_{i j}\right)$ and initial distribution $\pi$ that is also the stationary distribution of $Y$. We consider the hidden Markov model (HMM), in which to every state $l \in S$ there corresponds an emission distribution $P_{l}$ on $(\mathcal{X}, \mathcal{B})$. We assume $\mathcal{X}$ and $\mathcal{B}$ to be a separable metric space and the corresponding Borel $\sigma$-algebra, respectively. Let $f_{l}$ be the density of $P_{l}$ with respect to some reference measure $\lambda$ on $(\mathcal{X}, \mathcal{B})$, which one for concreteness may want to specialize to the Lebesgue measure.

In our model, to any realization $y_{1}, y_{2}, \ldots$ of $Y$ there corresponds a sequence of independent random variables, $X_{1}, X_{2}, \ldots$, where $X_{n}$ has the distribution $P_{y_{n}}$. We do not know the realizations $y_{n}$ (the Markov chain $Y$ is hidden), as we only observe the process $X=X_{1}, X_{2}, \ldots$, or, more formally:

Definition 2.1 We say that the stochastic process $X$ is a hidden Markov model if there is a (measurable) function $f$ such that for each $n$,

$$
\begin{equation*}
X_{n}=f\left(Y_{n}, e_{n}\right), \quad \text { where } e_{1}, e_{2}, \ldots \quad \text { are i.i.d. and independent of } Y . \tag{3}
\end{equation*}
$$

Hence, the emission distribution $P_{l}$ is the distribution of $f\left(l, e_{n}\right)$. The distribution of $X$ is completely determined by the chain parameters $(P, \pi)$ and the emission distributions $P_{l}, l \in S$. Moreover, the processes $Y$ and $X$ have the following properties:

- given $Y_{n}$, the observation $X_{n}$ is independent of $Y_{m}, m \neq n$. Thus, the conditional distribution of $X_{n}$ given $Y_{1}, Y_{2} \ldots$ depends on $Y_{n}$ only;
- the conditional distribution of $X_{n}$ given $Y_{n}$ depends only on the state of $Y_{n}$ and not on $n$;
- given $Y_{1}, \ldots, Y_{n}$, the random variables $X_{1}, \ldots, X_{n}$ are independent.

The process $X$ is also mixing and, therefore, ergodic.

### 2.2 Viterbi alignment and training

Suppose we observe $x_{1}, \ldots, x_{n}$, the first $n$ elements of $X$. Throughout the paper, we will also use the shorter notation $x_{1 \ldots n}$. A central concept of the paper is the Viterbi alignment, which is any sequence of states $q_{1 \ldots n} \in S^{n}$ that maximizes the likelihood of observing $x_{1 \ldots n .}$. In other words, the Viterbi alignment is a maximum-likelihood estimate of the realization of $Y_{1}, \ldots, Y_{n}$ given $x_{1}, \ldots, x_{n}$. In the following, the Viterbi alignment
will be referred to as the alignment. We start with the formal definition of the alignment. First note that for any sequence $q_{1 \ldots n} \in S^{n}$ of states and sets $B_{i} \in \mathcal{B} i=1, \ldots, n$,

$$
\mathbf{P}\left(X_{1} \in B_{1}, \ldots, X_{n} \in B_{n}, Y_{1}=q_{1}, \ldots, Y_{n}=q_{n}\right)=\mathbf{P}\left(Y_{1}=q_{1}, \ldots, Y_{n}=q_{n}\right) \prod_{i=1}^{n} \int_{B_{i}} f_{q_{i}} d \lambda
$$

and define $\Lambda\left(q_{1}, \ldots, q_{n} ; x_{1}, \ldots, x_{n}\right)$ to be the likelihood function:

$$
\Lambda\left(q_{1 \ldots n} ; x_{1 \ldots n}\right) \stackrel{\text { def }}{=} \mathbf{P}\left(Y_{i}=q_{i}, i=1, \ldots, n\right) \prod_{i=1}^{n} f_{q_{i}}\left(x_{i}\right) .
$$

Definition 2.2 For each $n \geq 1$, let the set of all the alignments be defined as follows:

$$
\begin{equation*}
\mathcal{V}\left(x_{1 \ldots n}\right)=\left\{v \in S^{n}: \forall w \in S^{n} \Lambda\left(v ; x_{1 \ldots n}\right) \geq \Lambda\left(w ; x_{1 \ldots n}\right)\right\} . \tag{4}
\end{equation*}
$$

Any map $v: \mathcal{X}^{n} \mapsto \mathcal{V}\left(x_{1 \ldots n}\right)$ as well as any element $v \in \mathcal{V}\left(x_{1}, \ldots, x_{n}\right)$ will also be called an alignment.

Note that alignments require the knowledge of all the parameters of $X:(\pi, P)$ and $P_{l}$ $\forall l \in S$.

Throughout the paper we assume that the sample $x_{1 \ldots n}$ is generated by an HMM with transition parameters $(\pi, P)$ and with the emission distributions $f_{i}\left(x ; \theta_{l}^{*}\right)$, where $\theta^{*}=$ $\left(\theta_{1}^{*}, \ldots, \theta_{K}^{*}\right)$ are the unknown true parameters. We assume that the transition parameters $P$ and $\pi$ are known, but the emission densities are known only up to the parametrization $f_{l}\left(\cdot ; \theta_{l}\right), \theta_{l} \in \Theta_{l}$. In this case, the likelihood function $\Lambda$ as well as the set of alignments $\mathcal{V}$ can be viewed as a function of $\theta$. In the following, we shall write $\mathcal{V}_{\theta}$ for the set of alignments using the parameters $\theta$. Also, unless explicitly specified, $v_{\theta} \in \mathcal{V}_{\theta}$ will denote an arbitrary element of $\mathcal{V}_{\theta}$.

The classical method for computing MLE of $\theta^{*}$ is the EM algorithm. However, if the dimension of $X$ is high, $n$ is big and $f_{i}$ 's are complex, then EM can be (and often is) computationally involved. For this reason, a shortcut, the so-called Viterbi training is used. The Viterbi training replaces the computationally expensive expectation (E-)step by an appropriate maximization step that is based on the alignment, and is generally computationally cheaper in practice than the expectation. We now describe the Viterbi training in the HMM case.
$\underline{\text { Viterbi training }}$

1. Choose an initial value $\theta^{o}=\left(\theta_{1}^{o}, \ldots, \theta_{K}^{o}\right)$.
2. Given $\theta^{j}$, obtain alignment

$$
v_{\theta^{j}}\left(x_{1 \ldots n}\right)=v_{1 \ldots n}
$$

and partition the sample $x_{1}, \ldots, x_{n}$ into $K$ sub-samples, where the observation $x_{k}$ belongs to the $l^{\text {th }}$ subsample if and only if $v_{k}=l$. Equivalently, we define (at most) $K$ empirical measures

$$
\begin{equation*}
\hat{P}_{l}^{n}\left(A ; \theta^{j}, x_{1 \ldots n}\right):=\frac{\sum_{i=1}^{n} I_{A \times l}\left(x_{i}, v_{i}\right)}{\sum_{i=1}^{n} I_{l}\left(v_{i}\right)}, \quad A \in \mathcal{B}, \quad l \in S \tag{5}
\end{equation*}
$$

3. For every sub-sample find MLE given by:

$$
\begin{equation*}
\hat{\mu}_{l}^{n}\left(\theta^{j}, x_{1 \ldots n}\right)=\arg \max _{\theta_{l} \in \Theta_{l}} \int \ln f_{l}\left(\theta_{l}, x\right) \hat{P}_{l}^{n}\left(d x ; \theta^{j}, x_{1 \ldots n}\right) \tag{6}
\end{equation*}
$$

and take

$$
\theta_{l}^{j+1}=\hat{\mu}_{l}\left(\theta^{j}, x_{1 \ldots n}\right), \quad l \in S
$$

If for some $l \in S v_{i} \neq l$ for any $i=1, \ldots, n$ ( $l^{\text {th }}$ subsample is empty), then the empirical measure $\hat{P}_{l}^{n}$ is formally undefined, in which case we take $\theta_{l}^{j+1}=\theta_{l}^{j}$. We will be omitting this exceptional case from now on.

The Viterbi training can be interpreted as follows. Suppose that at some step $j, \theta^{j}=\theta^{*}$ and hence $v_{\theta^{j}}$ is obtained using the true parameters. The training is then based on the assumption that the alignment $v_{1 \ldots n}=v\left(x_{1 \ldots n}\right)$ is correct, i.e., $v_{i}=Y_{i}, i=1, \ldots, n$. In this case, the empirical measures $\hat{P}_{l}^{n}, l \in S$ would be obtained from the i.i.d. sample generated from $P_{l}\left(\theta^{*}\right)$, and the MLE $\hat{\mu}_{l}{ }^{n}\left(\theta^{*}, X_{1 \ldots n}\right)$ would be a natural estimator to use. Clearly, under these assumptions $\hat{P}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right) \Rightarrow P_{l}\left(\theta^{*}\right)$ a.s. (" $\Rightarrow$ " denotes the weak convergence of probability measures) and, provided that $\left\{f_{l}(\cdot ; \theta): \theta \in \Theta_{l}\right\}$ is a $P_{l}$-Glivenko-Cantelli class and $\Theta_{l}$ is equipped with some suitable metric, $\lim _{n \rightarrow \infty} \hat{\mu}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right)=\theta_{l}^{*}$ a.s. Hence, if $n$ is sufficiently large, then $\hat{P}_{l}^{n} \approx P_{l}$ and

$$
\theta_{l}^{j+1}=\hat{\mu}_{l}^{n}\left(\theta^{*}, x_{1 \ldots n}\right) \approx \theta_{l}^{*}=\theta_{l}^{j}, \quad \forall l
$$

i.e. $\theta^{j}=\theta^{*}$ would be (approximately) a fixed point of the training algorithm.

A weak point of the foregoing argument is that the alignment in general is not correct even when the parameters used to find it, are. So, generally $v_{i} \neq Y_{i}$. In particular, this implies that the empirical measures $\hat{P}_{l}^{n}\left(\theta^{*}, x_{1 \ldots n}\right)$ are not obtained from an i.i.d. sample from $P_{l}\left(\theta^{*}\right)$. Hence, we have no reason to believe that $\hat{P}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right) \Rightarrow P_{l}\left(\theta^{*}\right)$ a.s. and $\lim _{n \rightarrow \infty} \hat{\mu}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right)=\theta_{l}^{*}$ a.s. Moreover, we do not even know whether the sequences of empirical measures $\left\{\hat{P}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right)\right\}$ and MLE estimators $\left\{\hat{\mu}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right)\right\}$ converge (a.s.) at all.

In this paper, we prove the existence of probability measures $Q_{l}\left(\theta, \theta^{*}\right)$ (that depend on both $\theta$, the parameters used to obtain the alignments, as well as $\theta^{*}$, the true parameters used to generate the training samples), $l \in S$, such that for every $l$

$$
\begin{equation*}
\hat{P}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right) \Rightarrow Q_{l}\left(\theta^{*}, \theta^{*}\right), \quad \text { a.s. } \tag{7}
\end{equation*}
$$

for a special choice of the alignment $v_{\theta^{*}} \in \mathcal{V}_{\theta^{*}}$ used to define $\hat{P}_{l}^{n}\left(\theta^{*}, x_{1 \ldots n}\right)$. (In fact, adding certain mild restrictions on $P_{l}$, one can eliminate the dependence of the above result on the particular choice of the alignment $v_{\theta^{*}} \in \mathcal{V}_{\theta^{*}}$. ) We will also be writing $Q_{l}(\theta)$ for $Q_{l}(\theta, \theta)$ whenever appropriate.

Suppose also that the parameter space $\Theta_{l}$ is equipped with some metric. Then, under certain consistency assumptions on classes $\mathcal{F}_{l}=\left\{f_{l}\left(\theta_{l}\right): \theta_{l} \in \Theta_{l}\right\}$, the convergence

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \hat{\mu}_{l}\left(\theta^{*}, X_{1 \ldots n}\right)=\mu_{l}\left(\theta^{*}\right) \quad \text { a.s. } \tag{8}
\end{equation*}
$$

can be deduced from (7), where

$$
\begin{equation*}
\mu_{l}(\theta) \stackrel{\text { def }}{=} \arg \max _{\theta_{l}^{\prime} \in \Theta_{l}} \int \ln f_{l}\left(x ; \theta_{l}^{\prime}\right) Q_{l}(d x ; \theta) \tag{9}
\end{equation*}
$$

We also show that in general, for the baseline Viterbi training $Q_{l}\left(\theta^{*}\right) \neq P_{l}\left(\theta^{*}\right)$, implying $\mu_{l}\left(\theta^{*}\right) \neq \theta_{l}^{*}$. In an attempt to reduce the bias $\theta_{l}^{*}-\mu_{l}\left(\theta^{*}\right)$, we next propose the adjusted Viterbi training.

Suppose (7) and (8) hold. Based on (9), we now consider the mapping

$$
\begin{equation*}
\theta \mapsto \mu_{l}(\theta), \quad l=1, \ldots, K \tag{10}
\end{equation*}
$$

The calculation of $\mu_{l}(\theta)$ can be rather involved and it may have no closed form. Nonetheless, since this function is independent of the sample, we can define the following correction for the bias:

$$
\begin{equation*}
\Delta_{l}(\theta)=\theta_{l}-\mu_{l}(\theta), \quad l=1, \ldots, K \tag{11}
\end{equation*}
$$

Thus, the adjusted Viterbi training emerges as follows:

## Adjusted Viterbi training

1. Choose an initial value $\theta^{0}=\left(\theta_{1}^{0}, \ldots, \theta_{K}^{0}\right)$.
2. Given $\theta^{j}$, perform the alignment and define $K$ empirical measures $\hat{P}_{l}^{n}\left(\theta^{j}, \theta^{*}\right)$ as in (5).
3. For every $\hat{P}_{l}^{n}\left(\theta^{j}, x_{1 \ldots n}\right)$, find $\hat{\mu}_{l}^{n}\left(\theta^{j}, x_{1 \ldots n}\right)$ as in (6).
4. For each $l$, define

$$
\theta_{l}^{j+1}=\hat{\mu}_{l}^{n}\left(\theta^{j}, x_{1 \ldots n}\right)+\Delta_{l}\left(\theta^{j}\right),
$$

where $\Delta_{l}$ as in (11).
Note that, as desired, for a sufficiently large $n$, the adjusted training algorithm has $\theta^{*}$ as its (approximately) fixed point: Indeed, suppose $\theta^{j}=\theta^{*}$, then $\hat{\mu}_{l}^{n}\left(\theta^{j}, x_{1 \ldots n}\right)=\hat{\mu}_{l}^{n}\left(\theta^{*}, x_{1 \ldots n}\right)$. Recalling (8), it then follows that $\hat{\mu}_{l}^{n}\left(\theta^{*}, x_{1 \ldots n}\right) \approx \mu_{l}\left(\theta^{*}\right)=\mu_{l}\left(\theta^{j}\right)$, for all $l \in S$. Hence,

$$
\begin{equation*}
\theta_{l}^{j+1}=\hat{\mu}_{l}\left(\theta^{*}, x_{1 \ldots n}\right)+\Delta_{l}\left(\theta^{*}\right) \approx \mu_{l}\left(\theta^{*}\right)+\Delta_{l}\left(\theta^{*}\right)=\theta_{l}^{*}=\theta^{j}, \quad l \in S \tag{12}
\end{equation*}
$$

In [10], we considered i.i.d. sequence $X_{1}, X_{2}, \ldots$, where $X_{1}$ has a mixture distribution, i.e. the density of $X_{1}$ is $\sum_{i=1}^{K} p_{i} f_{i}$. Here $p_{i}>0$ are the mixture weights. Such a sequence is an HMM with the transition matrix satisfying $p_{i j}=p_{j} \forall i, j$. In this particular case, the alignment and the measures $Q_{l}$ are easy to find. Indeed, for any set of parameters $\theta=\left(\theta_{1}, \ldots \theta_{K}\right)$, the alignment $v_{\theta}$ can be obtained via a Voronoi partition $\mathcal{S}(\theta)=\left\{S_{1}(\theta), \ldots, S_{K}(\theta)\right\}$, where

$$
\begin{align*}
S_{1}(\theta) & =\left\{x: p_{1} f_{1}\left(x ; \theta_{1}\right) \geq p_{j} f_{j}\left(x ; \theta_{j}\right), \quad \forall j \in S\right\}  \tag{13}\\
S_{l}(\theta) & =\left\{x: p_{l} f_{l}\left(x ; \theta_{l}\right) \geq p_{j} f_{j}\left(x ; \theta_{j}\right), \quad \forall j \in S\right\} \backslash\left(S_{1} \cup \ldots \cup S_{l-1}\right), \quad l=2, \ldots, K . \tag{14}
\end{align*}
$$

Now, the alignment can be defined pointwise as follows: $v_{\theta}\left(x_{1}, \ldots, x_{n}\right)=v_{\theta}\left(x_{1}\right) \cdots v_{\theta}\left(x_{n}\right)$, where $v_{\theta}(x)=l$ if and only if $x \in S_{l}(\theta)$.
The convergence (7) now follows immediately from the strong law of large numbers as $\hat{P}_{l}^{n}\left(\theta^{*}, X_{1 \ldots n}\right) \Rightarrow Q_{l}\left(\theta^{*}\right)$ a.s., where

$$
q_{l}\left(x ; \theta^{*}\right) \propto f\left(x ; \theta^{*}\right) I_{S_{l}\left(\theta^{*}\right)}=\left(\sum_{i} p_{i} f_{i}\left(x ; \theta^{*}\right)\right) I_{S_{l}\left(\theta^{*}\right)}, \quad l=1, \ldots, K
$$

are the densities of respective $Q_{l}\left(\theta^{*}\right)$.
Thus, in the special case of mixtures, the adjustments $\Delta_{l}$ are easy to calculate and the adjusted Viterbi training is easy to implement. Simulations in [10] have largely supported the expected gain in estimation accuracy due to the adjustment $\Delta$ with a small extra cost for computing $\Delta$. Indeed, this extra computation does not affect the algorithm's overall computational complexity as a function of the sample size, since $\Delta$ depends on the training sample only through $\theta^{j}$, the current value of the parameter.

Due to the time-dependence in the general HMM, the convergence (7) does not follow immediately from the law of large numbers. However, the very concept of the adjusted Viterbi training is based on the existence of the $Q_{l}$-measures. Thus, in order to generalize this concept to an arbitrary HMM, one has to begin with the existence of the $Q_{l}$-measures, which is the objective of this paper.

## 3 Nodes and barriers

In this section, we present some preliminaries that will allow us to prove the convergences (7) and (8). We choose to introduce the necessary concepts gradually, building up the general notions on special cases that we find more intuitive and insightful. For a comprehensive introduction to HMM's and related topics we refer to [7, 15, 16], and an overview of the basic concepts related to HMM's follows below in $\S 3.1$. We then proceed to the notion of infinite (Viterbi) alignment (§4.2), developing on the way several auxiliary notions such as nodes and barriers.

Throughout the rest of this section, we will be writing $f_{l}$ and $\mathcal{V}$ for $f_{l}\left(\cdot ; \theta_{l}^{*}\right)$, the true emission distributions, and $\mathcal{V}_{\theta^{*}}$, the set of alignments with the true parameters, respectively.

### 3.1 Nodes

### 3.1.1 Preliminaries

Let $1 \leq u_{1}<u_{2}<\ldots<u_{k} \leq n$. Given any sequence $a=\left(a_{1}, \ldots, a_{n}\right)$, write $a_{u_{1} \ldots u_{k}}$ for $\left(a_{u_{1}}, \ldots, a_{u_{k}}\right)$ and define also the following objects:

$$
S_{u_{1} \ldots u_{k}}^{l_{1} \ldots l_{k}}(n) \stackrel{\text { def }}{=}\left\{v \in S^{n}: v_{u_{1} \ldots u_{k}}=\left(l_{1}, \ldots, l_{k}\right)\right\}
$$

Next, given observations $x_{1 \ldots n}$, let us introduce the set of constrained likelihood maximizers defined below:

$$
\mathcal{W}_{u}^{l}\left(x_{1 \ldots n}\right)=\left\{v \in S_{u}^{l}(n): \forall w \in S_{u}^{l}(n) \Lambda\left(v ; x_{1 \ldots n}\right) \geq \Lambda\left(w ; x_{1 \ldots n}\right)\right\}
$$

Next, define the scores

$$
\begin{equation*}
\delta_{l}(u) \stackrel{\text { def }}{=} \max _{q \in S_{u}^{l}(u)} \Lambda\left(q ; x_{1 \ldots u}\right), \tag{15}
\end{equation*}
$$

and notice the trivial case: $\delta_{l}(1)=\pi_{l} f_{l}\left(x_{1}\right)$. Then, we have the following recursion (see, for example, [16]):

$$
\begin{equation*}
\delta_{j}(u+1)=\max _{l \in S}\left(\delta_{l}(u) p_{l j}\right) f_{j}\left(x_{u+1}\right) \tag{16}
\end{equation*}
$$

The Viterbi training as well as the Viterbi alignment inherit their names from the Viterbi algorithm, which is a dynamic programming algorithm for finding $v \in \mathcal{V}\left(x_{1 \ldots n}\right)$. In fact, due to potential non-uniqueness of such $v$, the Viterbi algorithm requires a selection rule as part of its specification. However, for our purposes we will often be manipulating by $\mathcal{V}\left(x_{1 \ldots n}\right)$ as opposed to by individual $v$ 's, in which case we will also be identifying the entire $\mathcal{V}\left(x_{1 \ldots n}\right)$ with the output of the algorithm. This algorithm is based on recursion (16) and on the following relations:

$$
\begin{align*}
t(u, j) & =\left\{l \in S: \forall i \in S \delta_{l}(u) p_{l j} \geq \delta_{i}(u) p_{i j}\right\}, \quad u=1, \ldots, n-1,  \tag{17}\\
\mathcal{V}\left(x_{1 \ldots n}\right) & =\left\{v \in S^{n}: \delta_{v_{n}}(n) \geq \delta_{i}(n) \forall i \in S, v_{u} \in t\left(u, v_{u+1}\right) 1 \leq u<n\right\} . \tag{18}
\end{align*}
$$

It can also be shown that

$$
\begin{equation*}
\mathcal{W}_{n}^{l}\left(x_{1 \ldots n}\right)=\left\{v \in S_{n}^{l}(n): v_{u} \in t\left(u, v_{u+1}\right) u=1, \ldots, n-1\right\} . \tag{19}
\end{equation*}
$$

We shall also need the following notation:

$$
\mathcal{V}_{u_{1} \ldots u_{k}}^{l_{1} \ldots l_{k}}\left(x_{1 \ldots n}\right)=\left\{v \in \mathcal{V}\left(x_{1 \ldots n}\right): v_{u_{i} u_{i+1} \ldots u_{k}}=\left(l_{1}, \ldots, l_{k}\right)\right\} .
$$

and will use subscript $(l)$ to refer to alignments obtained using $\left(p_{l i}\right)_{i \in S}$ (instead of $\pi$ ) as the initial distribution. Thus $\mathcal{V}_{(l)}\left(x_{1 \ldots n}\right)$ stands for the set of all such alignments, and

$$
\mathcal{V}_{(l) u_{1} \ldots u_{k}}^{l_{1} l_{k}}\left(x_{1 \ldots n}\right)=\left\{v \in \mathcal{V}_{(l)}\left(x_{1 \ldots n}\right): v_{u_{i} u_{i+1} \ldots u_{k}}=\left(l_{1}, \ldots, l_{k}\right)\right\} .
$$

Similarly, $\mathcal{W}_{(l) u_{1} \ldots u_{k}}^{l_{1} \ldots l_{k}}\left(x_{1 \ldots n}\right)$ will be referring to the constrained alignments obtained using $\left(p_{l i}\right)_{i \in S}$ as the initial distribution. The following Proposition and Corollary reveal more structure of the alignments.

Proposition 3.1 Let $1 \leq u \leq n$, then

$$
\begin{align*}
\mathcal{W}_{u}^{l}\left(x_{1 \ldots n}\right) & =\mathcal{W}_{u}^{l}\left(x_{1 \ldots u}\right) \times \mathcal{V}_{(l)}\left(x_{u+1 \ldots n}\right),  \tag{20}\\
\mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right) \neq \emptyset & \Rightarrow \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right)=\mathcal{W}_{u}^{l}\left(x_{1 \ldots n}\right) . \tag{21}
\end{align*}
$$

Proof. The Markov property implies: for any $q=\left(q_{1}, \ldots, q_{n}\right)$.

$$
\Lambda\left(q ; x_{1 \ldots n}\right)=\Lambda\left(q_{1 \ldots u} ; x_{1 \ldots u}\right) \cdot \Lambda\left(q_{u+1 \ldots n} ; x_{u+1 \ldots n} \mid q_{u}\right),
$$

where

$$
\Lambda\left(q_{u+1 \ldots n} ; x_{u+1 \ldots n} \mid l\right)=\mathbf{P}\left(Y_{u+1 \ldots n}=q_{u+1 \ldots n} \mid Y_{u}=l\right) \prod_{i=u+1}^{n} f_{q_{i}}\left(x_{i}\right)
$$

Thus, (20) follows from the equivalence between maximizing $\Lambda\left(q ; x_{1 \ldots n}\right)$ over $S_{u}^{l}(n)$ on one hand, and maximizing $\Lambda\left(q_{1 \ldots u} ; x_{1 \ldots u}\right)$ and $\Lambda\left(q_{u+1 \ldots n} ; x_{u \ldots n} \mid l\right)$ over $S^{n-u}$ and $S_{u}^{l}(n)$, respectively and independently, on the other. (21) follows immediately from the definitions of the involved sets.

## Corollary 3.1

$$
\begin{equation*}
\mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right) \neq \emptyset \text { and } \mathcal{V}_{u}^{l}\left(x_{1 \ldots u}\right) \neq \emptyset \Rightarrow \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right)=\mathcal{V}_{u}^{l}\left(x_{1 \ldots u}\right) \times \mathcal{V}_{(l)}\left(x_{u+1 \ldots n}\right) \tag{22}
\end{equation*}
$$

Proof. The hypotheses of (22) together with (21) imply $\mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right)=\mathcal{W}_{u}^{l}\left(x_{1 \ldots n}\right)$ and $\mathcal{V}_{u}^{l}\left(x_{1 \ldots u}\right)=\mathcal{W}_{u}^{l}\left(x_{1 \ldots u}\right)$. The latter statements and (20) yield the claim.

### 3.1.2 Nodes and alignment

We aim at extending the notion of alignment for infinite HMM's. In order to fulfil this objective, we investigate properties of finite alignments (e.g. Propositions 3.1, and 3.2) and identify necessary ingredients (e.g. "node", and "barrier") for the development of the extended theory. We start with the notion of nodes:

Figure 1: An example of the Viterbi algorithm in action. The solid line corresponds to the final alignment $v_{1 \ldots n}$. The dashed links are of the form $(k, l)-(k+1, j)$ with $l \in t(k, j)$ and are not part of the final alignment. E.g., $(1,3)-(2,2)-(3,3)$ is because $3 \in t(1,2), 2 \in t(2,3)$. The observation $x_{u}$ is a 2 -node, since we have $2 \in t(u, j) \forall j \in S$. We also see that $v_{1 \ldots u}$ is fixed.

Definition 3.1 For $1 \leq u<n$, we call $x_{u}$ an l-node if

$$
\begin{equation*}
\delta_{l}(u) p_{l j} \geq \delta_{i}(u) p_{i j}, \quad \forall i, j \in S \tag{23}
\end{equation*}
$$

We also say that $x_{u}$ is a node if it is an l-node for some $l \in S$.
Figure 1 illustrates the newly introduced notion.

## Proposition 3.2

$$
\begin{align*}
x_{u} \text { is an } l \text {-node } & \Longleftrightarrow l \in t(u, j) \forall j \in S,  \tag{24}\\
& \Rightarrow \mathcal{V}_{u}^{l}\left(x_{1 \ldots u}\right) \neq \emptyset,  \tag{25}\\
& \Rightarrow \forall v \in \mathcal{V}\left(x_{1 \ldots n}\right), \forall v^{*} \in \mathcal{V}_{u}^{l}\left(x_{1 \ldots u}\right)\left(v^{*}, v_{u+1 \ldots n}\right) \in \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right),  \tag{26}\\
& \Rightarrow \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right) \neq \emptyset,  \tag{27}\\
& \Rightarrow \text { Right hand side of }(22) . \tag{28}
\end{align*}
$$

Whether $x_{u}$ is a node does not depend on $x_{i}, i>u$.
Proof. The final statement follows immediately from Definition 3.1 and (15), and (24) also follows immediately from Definition 3.1 and (17). Summing both sides of (23) over $j \in S$, we obtain

$$
\begin{equation*}
\delta_{l}(u) \geq \delta_{i}(u), \quad \forall i \in S, \tag{29}
\end{equation*}
$$

hence, (25) holds by (18). Note that (26) means that any alignment $v \in \mathcal{V}\left(x_{1 \ldots n}\right)$ can be modified by setting $v_{u}=l$ and taking $v_{i}^{*} \in t\left(i, v_{i+1}\right)$ for $i=u-1, u-2, \ldots, 1$, and the modified string remains an alignment, i.e. belongs to $\mathcal{V}\left(x_{1 \ldots n}\right)$. Such a modification is
evidently always possible, i.e., $\left(v^{*}, v_{u+1 \ldots n}\right)$ is well-defined since $\mathcal{V}_{u}^{l}\left(x_{1 \ldots u}\right) \neq \emptyset$. For $u=n$ this holds trivially, for $u<n$ this follows from (24) (as the latter implies $l \in t\left(u, v_{u+1}\right)$ for any value of $v_{u+1}$ ), and (18). Also, (26) implies (27). Finally, given (25) and (27), Corollary 3.1 yields (28).

Remark 3.2 Note that a modification of $v \in \mathcal{V}\left(x_{1 \ldots x_{n}}\right)$ possibly required to enforce $v_{u}=l$ when $x_{u}$ is an l-node (see proof of (26) above) depends only on $x_{1}, \ldots, x_{u-1}$. Thus, if $x_{u}$ is an $l$-node and if $v^{*} \in \mathcal{V}_{u}^{l}\left(x_{1 \ldots x_{u}}\right)$, then for any $n>u$ and any $x_{u+1}, \ldots, x_{n}(26)$ always guarantees an alignment $v \in \mathcal{V}\left(x_{1 \ldots n}\right)$ with $v_{1 \ldots u}=v^{*}$, in which case we can call $v^{*}$ fixed, meaning that $v^{*}$ can be kept as the substring of the first $u$ components for any alignment based on the extended observations.

The fact that $v \in \mathcal{V}\left(x_{1 \ldots n}\right)$ in general does not imply $v_{1 \ldots u} \in \mathcal{V}\left(x_{1 \ldots u}\right)$ complicates the structure of the alignments and furthermore emphasizes the significance of nodes in view of (28) and Remark 3.2.

Corollary 3.2 Suppose the observations $x_{1}, \ldots, x_{n}$ are such that for some $1 \leq u_{1}<u_{2}<$ $\cdots<u_{k} \leq n$, the observations $x_{u_{i}}$ are $l_{i}$-nodes, $i=1, \ldots, k-1$. Then

$$
=\mathcal{V}_{u_{1}}^{l_{1}}\left(x_{1 \ldots u_{1}}\right) \times \mathcal{V}_{\left(l_{1}\right) u_{2}}^{l_{2}}\left(x_{u_{1}+1 \ldots u_{2}}\right) \times \cdots \times \mathcal{V}_{\left(l_{k-1}\right) u_{k}}^{l_{k}}\left(x_{u_{k-1}+1 \ldots u_{k}}\right) \times \mathcal{V}_{u_{1} u_{2} \ldots u_{k}}^{l_{1} l_{2} \ldots l_{k}}\left(x_{1 \ldots n)}\right)=
$$

Proof. By (25),

$$
\mathcal{V}_{u_{i}}^{l_{i}}\left(x_{1 \ldots u_{i}}\right) \neq \emptyset, \quad i=1, \ldots, k
$$

By (27)

$$
\mathcal{V}_{u_{k}}^{l_{k}}\left(x_{1 \ldots n}\right) \neq \emptyset, \quad \mathcal{V}_{u_{i}}^{l_{i}}\left(x_{1 \ldots u_{i+1}}\right) \neq \emptyset \quad i=1, \ldots, k-1
$$

From (26), it now follows

$$
\mathcal{V}_{u_{i} u_{i+1}}^{l_{i} l_{i+1}}\left(x_{1 \ldots u_{i+1}}\right) \neq \emptyset, \quad i=2, \ldots k-1
$$

Now use (22) to decompose

$$
\mathcal{V}_{u_{k}}^{l_{k}}\left(x_{1 \ldots n}\right)=\mathcal{V}_{u_{k}}^{l_{k}}\left(x_{1 \ldots u_{k}}\right) \times \mathcal{V}_{\left(l_{k}\right)}\left(x_{u_{k}+1 \ldots n}\right)
$$

Use (22) again to decompose

$$
\mathcal{V}_{u_{k-1} u_{k}}^{l_{k-1} l_{k}}\left(x_{1 \ldots u_{k}}\right)=\mathcal{V}_{u_{k-1}}^{l_{k-1}}\left(x_{1 \ldots u_{k-1}}\right) \times \mathcal{V}_{\left(l_{k-1}\right) u_{k}}^{l_{k}}\left(x_{u_{k-1}+1 \ldots u_{k}}\right)
$$

Proceeding this way, we obtain (30).
Corollary 3.2 guarantees the existence of an alignment $v\left(x_{1 \ldots n}\right)$ that can be constructed piecewise, i.e.

$$
\begin{equation*}
\left(v_{1}, \ldots, v_{k+1}\right) \in \mathcal{V}\left(x_{1 \ldots n}\right), \tag{31}
\end{equation*}
$$

where
$v_{1} \in \mathcal{V}_{u_{1}}^{l_{1}}\left(x_{1 \ldots u_{1}}\right), v_{2} \in \mathcal{V}_{\left(l_{1}\right) u_{2}}^{l_{2}}\left(x_{u_{1}+1 \ldots u_{2}}\right), \ldots, v_{k} \in \mathcal{V}_{\left(l_{k-1}\right) u_{k}}\left(x_{u_{k-1}+1 \ldots u_{k}}\right), v_{k+1} \in \mathcal{V}_{\left(l_{k}\right)}\left(x_{u_{k}+1 \ldots u_{n}}\right)$.

### 3.1.3 Proper alignment

If the sets $\mathcal{V}_{\left(l_{i-1}\right) u_{i}}^{l_{i}}\left(x_{u_{i-1}+1 \ldots u_{i}}\right), i=2, \ldots, k$ as well as $\mathcal{V}_{\left(l_{k}\right)}\left(x_{u_{k}+1 \ldots n}\right)$ have a single element each, then the concatenation (31) is unique. Otherwise, a single $v_{i}$ will need to be selected from $\mathcal{V}_{\left(l_{i-1}\right) u_{i}}^{l_{i}}\left(x_{u_{i-1}+1 \ldots u_{i}}\right)$. Thus, suppose that $\left(x_{u_{i-1}+1 \ldots u_{i}}\right)=\left(x_{u_{j-1}+1 \ldots u_{j}}\right)$, and $l_{i}=l_{j}$ for some $j \neq i$. Ignoring the fact that the actual probability of such realizations may well be zero in most cases, for technical reasons we are nonetheless going to be general and require that the selection from any $\mathcal{V}_{(q) u+\Delta}^{l}\left(x_{u+1 \ldots u+\Delta}\right)$ for which $x_{u}$ and $x_{u+\Delta}$ are $q$ and $l$ nodes, respectively, be made independently of $u$. To achieve this, we impose the following (formally even more restrictive) condition on admissible selection schemes $\left\{w^{q l}\left(x_{1 \ldots m}\right): \mathbb{R}^{m} \rightarrow \mathcal{W}_{(q) m}^{l}\left(x_{1 \ldots m}\right), m=1, \ldots, n, q, l \in S\right\}:$

$$
\begin{equation*}
\forall q, \forall l \in S, \forall m \leq n, \forall x_{1 \ldots n} \in \mathbb{R}^{n}: w_{1 \ldots n}=w^{q l}\left(x_{1 \ldots n}\right) \Rightarrow w_{1 \ldots m}=w^{q w_{m}}\left(x_{1 \ldots m}\right) . \tag{32}
\end{equation*}
$$

The condition (32) above simply states that the ties are broken consistently.
Definition 3.3 The alignment (31) based on $l_{1}, \ldots, l_{k}$ nodes $x_{u_{1}}, \ldots, x_{u_{k}}$ is called proper if for every $i=2, \ldots, k-1$

$$
v_{i}=w^{l_{i} l_{i+1}}\left(x_{u_{i}+1 \ldots u_{i+1}}\right),
$$

where $\left\{w^{q l}\left(x_{1 \ldots m}\right): \mathbb{R}^{m} \rightarrow \mathcal{W}_{(q) m}^{l}\left(x_{1 \ldots m}\right), m=1, \ldots, n, q, l \in S\right\}$ is some selection scheme satisfying (32).

Clearly, there may be many such selection schemes and the following discussion is valid for all of them (provided the choice is fixed throughout). One such selection scheme is based on taking maxima under the reverse lexicographic order on $S^{m}$ (for any positive integer $m$ ). According to this order $\prec$, for $a, b \in S^{m}, a \prec b$ if and only if for some $i$, $1 \leq i<m, a_{i}<b_{i}$ and $a_{j}=b_{j}$ for $j=i+1, \ldots, m$. (Clearly, if neither $a \prec b$ nor $b \prec a$, then $a_{j}=b_{j}$ for $j=1, \ldots, m$, in which case $a$ and $b$ are defined equal for this order.) It is immediate to verify that (32) holds for

$$
\begin{equation*}
w^{q l}\left(x_{1 \ldots m}\right) \stackrel{\text { def }}{=} \max _{\prec} \mathcal{W}_{(q) m}^{l}\left(x_{1 \ldots m}\right), 1 \leq m \leq n, q, l \in S . \tag{33}
\end{equation*}
$$

For the sake of concreteness, we are going to refer to this particular selection scheme as the selection and base all proper alignments on it. Also, since Definition 3.3 does not concern the initial or terminal components of the concatenated alignment (31), we extend the selection (again, purely for the sake of concreteness of the presentation) to the initial and terminal components of the concatenated alignment (31). Thus, to specify the initial component we have $w^{\pi l}\left(x_{1 \ldots m}\right) \stackrel{\text { def }}{=} \max _{\prec} \mathcal{W}_{m}^{l}\left(x_{1 \ldots m}\right), 1 \leq m \leq n$, for all $l \in S$ and for all $\pi$, probability mass functions on $S$. To be concise, we will write $\vee W$ for the selected element of $W$ for any $W \subset S^{m}$ (where $W$ generally depends on $x_{1 \ldots m}$ ). In particular, the final component is then specified via $\vee \mathcal{V}_{(l)}\left(x_{1 \ldots m}\right)$.

Example 3.4 Consider an i.i.d. sequence $X_{1}, X_{2}, \ldots$, where $X_{1}$ has a mixture distribution, i.e. the density of $X_{1}$ is $\sum_{i=1}^{K} p_{i} f_{i}$. Here $p_{i}>0$ are the mixture weights. Such a sequence is an HMM with the transition matrix satisfying $p_{i j}=p_{j} \forall i, j$. In this case, an observation $x_{u}$ is an l-node if

$$
\delta_{l}(u) \geq \delta_{i}(u), \quad \forall i
$$

In particular, this means that every observation is an l-node for some $l \in S$. Then (16) becomes

$$
\delta_{i}(u+1)=\max _{j}\left(\delta_{j}(u)\right) p_{i} f_{i}\left(x_{u+1}\right) \propto p_{i} f_{i}\left(x_{u+1}\right), \quad \forall i
$$

and

$$
\begin{equation*}
\delta_{l}(u) \geq \delta_{i}(u), \quad \forall i \quad \Longleftrightarrow \quad p_{l} f_{l}\left(x_{u}\right) \geq p_{i} f_{i}\left(x_{u}\right), \quad \forall i \tag{34}
\end{equation*}
$$

Thus, in a mixture-model, any observation $x_{u}$ is a node, more precisely it is an l-node for any $l=\arg \max _{j}\left(p_{j} f_{j}\left(x_{u}\right)\right)$. For this model, the alignment can naturally be concatenated pointwise: $v\left(x_{1 \ldots n}\right)=\left(v\left(x_{1}\right), \ldots, v\left(x_{n}\right)\right)$, where

$$
\begin{equation*}
v(x)=\arg \max _{i} p_{i} f_{i}(x) \tag{35}
\end{equation*}
$$

The alignment will be proper if ties in (35) are broken consistently, which is, for example, the case when using the selection (33).

## $3.2 r^{\text {th }}$-order nodes

The concept of nodes is both important and rich, but the existence of a node can also be restrictive in the following sense: Suppose $x_{1 \ldots u}$ is such that $\delta_{i}(u)>0$ for every $i$. In this case, (23) is equivalent to

$$
\delta_{l}(u) \geq \max _{i}\left(\max _{j}\left(\frac{p_{i j}}{p_{l j}}\right) \delta_{i}(u)\right)
$$

and actually implies $p_{l j}>0$ for every $j \in S$. Hence, one cannot guarantee the existence of an $l$-node for an arbitrary emission distribution since an ergodic $P$ in general can have a zero in every row, violating the above positivity constraint on the $l^{\text {th }}$ row of $P$. We now generalize the notion of nodes in order to eliminate the aforementioned positivity constraint and to still enjoy the desirable properties of nodes. We need some additional definitions: For each $u \geq 1$ and $r \geq 1$, let

$$
\begin{equation*}
p_{i j}^{(r)}(u)=\max _{q_{1} \ldots r \in S^{r}} p_{i q_{1}} f_{q_{1}}\left(x_{u+1}\right) p_{q_{1} q_{2}} f_{q_{2}}\left(x_{u+2}\right) p_{q_{2} q_{3}} \ldots p_{q_{r-1} q_{r}} f_{q_{r}}\left(x_{u+r}\right) p_{q_{r} j} \tag{36}
\end{equation*}
$$

Also, for each $u \geq 1$ define $p_{i j}^{(0)}(u)=p_{i j}$, and notice

$$
p_{i j}^{(r)}(u)=\max _{q \in S} p_{i q}(u) f_{q}\left(x_{u+1}\right) p_{q j}^{(r-1)}(u+1)
$$

The recursion (16) then generalizes to

$$
\delta_{j}(u+1)=\max _{i}\left(\delta_{i}(u-r) p_{i j}^{(r)}(u-r)\right) f_{j}\left(x_{u+1}\right), r<u
$$

For $r \geq 1$ and $u+r \leq n$ define

$$
\begin{align*}
t^{(r)}(u, j) & =\left\{l \in S: \forall i \in S \delta_{l}(u) p_{l j}^{(r-1)} \geq \delta_{i}(u) p_{i j}^{(r-1)}\right\}  \tag{37}\\
t^{(r)}(u, J) & =\left\{t^{(r)}(u, j): j \in J\right\}, \quad J \subset S
\end{align*}
$$

Figure 2: In this example, $x_{u}$ is a $2^{d}$ order 2 -node, $x_{u-1}$ is a $3^{d}$-order 3 -node. Thus, for given $x_{1 \ldots n}$, the alignment includes $v_{u}=2$. However, unlike in the case of ordinary nodes (of order 0), $x_{u+1}$ can now destroy the property of $x_{u}$ being the (second order) node.

It can be verified that for $1 \leq q, r, q+r \leq n-u$

$$
\begin{equation*}
t^{(r+q)}(u, j)=t^{(q)}\left(u, t^{(r)}(u+q, j)\right) \tag{38}
\end{equation*}
$$

where $t^{(1)}(u, j)$ coincides with $t(u, j)(18)$. Thus, $l_{1} \in t^{(q)}\left(u, t^{(r)}(u+q, j)\right)$ in (38) implies the existence of $l_{2} \in t^{(r)}(u+q, j)$ such that $l_{1} \in t^{(q)}\left(u, l_{2}\right)$. In short,

$$
t^{(q)}\left(u, t^{(r)}(u+q, j)\right)=\cup_{l \in t^{(r)}(u+q, j)} t^{(q)}(u, l) .
$$

Note that with this new notation, (18) and (19) can be rewritten respectively as follows:

$$
\begin{align*}
\mathcal{V}\left(x_{1}, \ldots, x_{n}\right) & =\left\{v \in S^{n}: \delta_{v_{n}}(n) \geq \delta_{i}(n) \forall i \in S, v_{u} \in t^{(n-u)}\left(u, v_{n}\right) 1 \leq u<n\right\}  \tag{39}\\
\mathcal{W}_{u}^{l}\left(x_{1}, \ldots, x_{n}\right) & =\left\{v \in S_{n}^{l}(n): v_{u} \in t^{(n-u)}(u, l) 1 \leq u<n\right\} \tag{40}
\end{align*}
$$

We now generalize the concept of the node:
Definition 3.5 Let $1 \leq r<n, u \leq n-r$ and let $l \in S$. We call $x_{u}$ an l-node of order $r$ if

$$
\begin{equation*}
\delta_{l}(u) p_{l j}^{(r)}(u) \geq \delta_{i}(u) p_{i j}^{(r)}(u), \quad \forall i, j \in S \tag{41}
\end{equation*}
$$

We also say that $x_{u}$ is a node of order $r$ if it is an l-node of order $r$ for some $l \in S$.
Note that a $0^{t h}$-order node is just a node. One immediately obtains the following properties of the (generalized) nodes:

Proposition 3.3 Let $0 \leq r, 1 \leq q$ such that $r+q \leq n-u$, then

1. If $x_{u}$ is an $r^{\text {th }}$-order l-node, then it is also an l-node of order $r+q$.
2. If $x_{u+q}$ is an $r^{\text {th }}$-order $l$-node, then $x_{u}$ is an $(r+q)^{\text {th }}$-order $l^{\prime}$-node for any $l^{\prime} \in$ $t^{(q)}(u, l)$.

Next, we generalize Proposition 3.2:

## Proposition 3.4

$$
\begin{align*}
& x_{u} \text { is an l-node of order } r \Longleftrightarrow l \in t^{(r+1)}(u, j) \forall j \in S,  \tag{42}\\
& u+r<n, x_{u} \text { is an l-node of order } r \Rightarrow \forall v \in \mathcal{V}\left(x_{1 \ldots n}\right), \forall v^{*} \in \mathcal{W}_{u}^{l}\left(x_{1 \ldots u}\right) \\
& \exists v^{\prime} \in \mathcal{W}_{u}^{l} v_{u+r+1} u+1  \tag{43}\\
&\left.v_{1 \ldots u+r+1}\right) v^{*}=v_{1 \ldots u}^{\prime},\left(v^{\prime}, v_{u+r+1 \ldots n}\right) \in \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right),  \tag{44}\\
& \Rightarrow \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right) \neq \emptyset  \tag{45}\\
& \Rightarrow \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right)=\mathcal{W}_{u}^{l}\left(x_{1 \ldots u}\right) \times \mathcal{V}_{(l)}\left(x_{u+1 \ldots n}\right) .
\end{align*}
$$

Finding $v_{u+1 \ldots u+r}^{\prime}$ and $v^{*} \in \mathcal{W}_{u}^{l}\left(x_{1 \ldots u}\right)$ in (43) for given $v \in \mathcal{V}\left(x_{1 \ldots n}\right)$ does not require knowledge of any of $x_{u+r+1 \ldots n}$. Finally, whether $x_{u}$ is an l-node of order $r$ depends on $x_{1}, \ldots, x_{u+r}$ only, i.e. it does not depend on any $x_{i}$ for $i>u+r$.
Proof. The final statement follows immediately from Definition 3.5 and relations (15) and (36). (42) also follows immediately from Definition 3.5 and (37). In order to see (43), note that applying (38) with $q=1$ to $l \in t^{(r+1)}\left(u, v_{u+r+1}\right)$ once gives us $\tilde{v}_{1} \in t^{(r)}\left(u+1, v_{u+r+1}\right)$. Applying then (38) with $q=1$ to $\tilde{v}_{i} \in t^{(r-i+1)}\left(u+i, v_{u+r+1}\right)$ successively for $i=2, \ldots, r$ proves the existence of the entire $\tilde{v}_{1 \ldots r} \in S^{r}$ such that $l \in \tilde{t}\left(u, v_{1}^{\prime}\right), \tilde{v}_{1}^{\prime} \in t\left(u+1, \tilde{v}_{2}\right), \ldots$, $\tilde{v}_{r-1} \in t\left(u+r-1, \tilde{v}_{r}\right), \tilde{v}_{r} \in t\left(u, v_{u+r+1}\right)$. Thus, recalling (40), $\tilde{v}=v_{u+1 \ldots u+r}^{\prime}$ for some $v^{\prime} \in \mathcal{W}_{u u+r+1}^{l} v_{u+r+1}\left(x_{1 \ldots u+r+1}\right)$. Since $v_{i}^{*} \in t\left(i, v_{i+1}^{*}\right)$ for $i=1, \ldots, u-1\left(v^{*} \in \mathcal{W}_{u}^{l}\left(x_{1 \ldots u}\right)\right.$ and (19)), and $v_{i} \in t\left(i, v_{i+1}\right)$ for $i=u+r+1, \ldots, n-1$ and $\delta_{v_{n}}(n) \geq \delta_{j}(n) \forall j \in S\left(v \in \mathcal{V}\left(x_{1 \ldots n}\right)\right.$ and (18)), one gets $\left(v^{*}, v^{\prime}, v_{u+r+1 \ldots n}\right) \in \mathcal{V}_{u}^{l}\left(x_{1 \ldots n}\right)$. Evidently, $v^{\prime}$ above involves no $x_{i}$ for $i>u+r$. Thus, unlike in (26), in addition to setting $v_{u}=l$ and taking $v_{i}^{*} \in t\left(i, v_{i+1}\right)$ for $i=u-1, u-2, \ldots, 1$ we may have to "realign" $u+1^{\text {st }}, \ldots, u+r^{\text {th }}$ components in order for the modified string to remain in $\mathcal{V}\left(x_{1 \ldots n}\right)$. Moreover, $v^{*}$ need not belong to $\mathcal{V}\left(x_{1 \ldots u}\right)$. Clearly, (43) implies (44). Finally, given (44), Proposition 3.1 yields (45).

Corollary 3.3 For any fixed $s \in S$, Proposition 3.4 remains valid after replacing $\pi$ by $\left(p_{s i}\right)_{i \in S}$, wherever appropriate. In particular,

$$
\begin{aligned}
u+r<n, x_{u} \text { is an } l \text {-node of order } r \Rightarrow & \emptyset \neq \mathcal{V}_{(s) u}^{l}\left(x_{1 \ldots n}\right)= \\
& =\mathcal{W}_{(s) u}^{l}\left(x_{1 \ldots u}\right) \times \mathcal{V}_{(l)}\left(x_{u+1 \ldots n}\right)
\end{aligned}
$$

Corollary 3.4 Let $u_{i}+r_{i}<u_{i+1} i=1, \ldots, k-1$, and $u_{k}+r_{k}<n$, and suppose $x_{1 \ldots n}$ is such that the observations $x_{u_{i}}$ are $l_{i}$-nodes of order $r_{i}$, for $i=1, \ldots, k$. Then

$$
=\mathcal{W}_{u_{1}}^{l_{1}}\left(x_{1 \ldots u_{1}}\right) \times \mathcal{W}_{\left(l_{1}\right) u_{2}}^{l_{2}}\left(x_{u_{1}+1 \ldots u_{2}}\right) \times \cdots \times \mathcal{W}_{\left(l_{k-1}\right) u_{k}}^{l_{k}}\left(x_{u_{k-1}+1 \ldots u_{k}}\right) \times \mathcal{V}_{\left(l_{k}\right)}^{\mathcal{U}_{1} l_{1} l_{2} \ldots l_{k}}\left(x_{u_{k}+1 \ldots n}\right) .
$$

Proof. By (44), we have

$$
\mathcal{V}_{u_{i}}^{l_{i}}\left(x_{1 \ldots n}\right) \neq \emptyset \quad i=1, \ldots, k
$$

Hence,

$$
\emptyset \neq \mathcal{V}_{u_{1} u_{2} \cdots u_{k}}^{l_{1} l_{2} \cdots l_{k}}\left(x_{1 \ldots n}\right) .
$$

By (45),

$$
\mathcal{V}_{u_{1} u_{2} \cdots u_{k}}^{l_{1} l_{2} \cdots l_{k}}\left(x_{1 \ldots n}\right)=\mathcal{W}_{u_{1}}^{l_{1}}\left(x_{1 \ldots u_{1}}\right) \times \mathcal{V}_{\left(l_{1}\right) u_{2} \cdots u_{k}}^{l_{2} \cdots l_{k}}\left(x_{u_{1}+1 \ldots n}\right) .
$$

Apply Corollary 3.3 to get

$$
\mathcal{V}_{\left(l_{1}\right) u_{2} \cdots u_{k}}^{l_{2} \cdots l_{k}}\left(x_{u_{1}+1 \ldots n}\right)=\mathcal{W}_{\left(l_{1}\right) u_{2}}^{l_{2}}\left(x_{u_{1}+1 \ldots u_{2}}\right) \times \mathcal{V}_{\left(l_{2}\right) u_{3} \cdots u_{k}}^{l_{3} \cdots l_{k}}\left(x_{u_{2}+1 \ldots n}\right),
$$

and repeat similarly to get

$$
\mathcal{V}_{\left(l_{i}\right) u_{i+1} \cdots u_{k}}^{l_{i+1} \cdots l_{k}}\left(x_{u_{i}+1 \ldots n}\right)=\mathcal{W}_{\left(l_{i}\right) u_{i+1}}^{l_{i+1}}\left(x_{u_{i}+1 \ldots u_{i+1}}\right) \times \mathcal{V}_{\left(l_{i+1}\right) u_{i+2} \cdots u_{k}}^{l_{i+2} \cdots l_{k}}\left(x_{u_{i+1}+1 \ldots n}\right)
$$

for $i=2, \ldots, k-1$, yielding the desired result.
Thus, the assumptions of Proposition 3.4 and Corollary 3.4 establish the existence of piecewise alignments

$$
\begin{equation*}
v=\left(v_{1}, \ldots, v_{k+1}\right) \in \mathcal{V}\left(x_{1 \ldots n}\right), \tag{47}
\end{equation*}
$$

where $v_{1} \in \mathcal{W}_{u_{1}}^{l_{1}}\left(x_{1 \ldots u_{1}}\right), v_{2} \in \mathcal{W}_{\left(l_{1}\right) u_{2}}^{l_{2}}\left(x_{u_{1}+1 \ldots u_{2}}\right), \ldots, v_{k} \in \mathcal{W}_{\left(l_{k-1}\right) u_{k}}^{l_{k}}\left(x_{u_{k-1}+1 \ldots u_{k}}\right), v_{k+1} \in$ $\mathcal{V}_{\left(l_{k}\right)}\left(x_{u_{k}+1 \ldots n}\right)$. Moreover, for every $i=1, \ldots, k$, the vectors $w(i) \stackrel{\text { def }}{=}\left(v_{1}, \ldots, v_{i}\right)$ satisfy $w(i) \in \mathcal{W}_{u_{i}}^{l_{i}}\left(x_{1 \ldots u_{i}}\right)$ and $w(i)_{1 \ldots u_{i-1}}=w(i-1), \quad i=2, \ldots, k$. Since $w(i)$ does not depend on $x_{u_{i}+r_{i}+1}, \ldots, x_{n}$ and as long as $x_{1}, \ldots, x_{u_{i}+r_{i}}$ are such that $x_{u_{i}}$ is a node of order- $r_{i}$, an alignment $v\left(x_{1 \ldots n}\right)$ can always be found such that $v_{1 \ldots u_{i}}=w(i)$.

Definition 3.6 Any alignment of the form in (47) is called a piecewise alignment based on nodes $x_{u_{1}}, \ldots, x_{u_{k}}$ of orders $r_{1}, \ldots, r_{k}$, respectively.
Recall that we have previously fixed the selection scheme $\vee$ (33). Based on this selection scheme, we will concern ourselves in $\S 4.2$ with proper (Definition 3.3) piecewise (Definition 3.6) alignments (that are based on nodes of possibly non-zero orders) formally defined as follows:

## Definition 3.7

$$
\begin{aligned}
v\left(x_{1 \ldots n}\right) \stackrel{\text { def }}{=} & \left(\vee \mathcal{W}_{u_{1}}^{l_{1}}\left(x_{1 \ldots u_{1}}\right), \vee \mathcal{W}_{\left(l_{1}\right) u_{2}}^{l_{2}}\left(x_{u_{1}+1 \ldots u_{2}}\right), \ldots,\right. \\
& \left.\vee \mathcal{W}_{\left(l_{k-1}\right) u_{k}}^{l_{k}}\left(x_{u_{k-1}+1 \ldots u_{k}}\right), \vee \mathcal{V}_{\left(l_{k}\right)}\left(x_{u_{k}+1 \ldots n}\right)\right) \in \mathcal{V}_{u_{1} \ldots u_{k}}^{l_{1} \ldots l_{k}}\left(x_{1 \ldots n}\right),
\end{aligned}
$$

for $k>0$, and $v\left(x_{1 \ldots n}\right) \stackrel{\text { def }}{=} \vee \mathcal{V}\left(x_{1 \ldots n}\right)$ for $k=0$.
To summarize the above, recall that by defining nodes (of various orders) we aim at extending alignments at infinitum, and we would like to do this for as wide class of HMMs with irreducible and aperiodic hidden layers as possible. Having $l$-nodes of order 0 im mediately restricts the transition probabilities by requiring $p_{l j}>0$ for $\forall j \in S$. However, this restriction disappears with the introduction of nodes of order $r$ for sufficiently large $r$. Indeed, suppose that $\forall u 0<u \leq n, \delta_{j}(u)>0 \forall j \in S$ (which in particular implies $\left.f_{j}\left(x_{u}\right)>0 \forall j \in S \forall u 0<u \leq n\right)$. Then, $x_{u}$ being an $l$-node of order $r$ and irreducibility of the underlying chain imply $p_{l j}^{(r)}(u)>0 \forall j \in S$. The latter in turn implies that $r_{l j}>0$ for every $j \in S$, where $r_{l j}$ is the entry $l j$ of $P^{r}$. Thus, having an $l$-node of order $r$ for some $r$ does not impose any restriction on $P$ : by virtue of irreducibility and aperiodicity of $P$, there always exists $r_{0}$ such that $P^{r}$ has all of its entries positive for every $r \geq r_{0}$.

### 3.3 Barriers

By Corollary 3.4, $x_{u}$ being a node of order $r$ fixes the alignment up to $u$ for any possible continuation of $x_{1 \ldots u+r}$. However, changing the value of an observation before $x_{u+r+1}$, say $x_{1}$ or $x_{u+r}$, can prevent $x_{u}$ from being the node. Moreover, in general nothing guarantees that for an arbitrary prefix $x_{1 \ldots w}^{\prime} \in S^{w}, w+u$-th element of $\left(x_{1 \ldots w}^{\prime}, x_{1 \ldots u+r}\right)$ would be a node of order $r$. On the other hand, a block of observations $y_{1 \ldots k} \in S^{k}(k \geq r)$ can be such that for any $w>0$ and for any $x_{1 \ldots w}^{\prime} \in S^{w}, w+k-r$-th element of $\left(x_{1 \ldots w}^{\prime}, y_{1 \ldots k}\right)$ is a node of order $r . y_{1 \ldots k}$ in that case will be called a barrier.

Definition 3.8 A block of observations $y_{1 \ldots k} \in \mathcal{X}^{k}(k \geq r)$ is called an l-barrier of order $r$ if for any $w>0$ and for any $x_{1 \ldots w}^{\prime} \in \mathcal{X}^{w}, w+k-r$-th element of $\left(x_{1 \ldots w}^{\prime}, y_{1 \ldots k}\right)$ is an $l$-node of order $r$.

### 3.4 Existence of barriers

In this section, we state the main technical result of the paper. For each $i \in S$, we denote by $G_{i}$ the support of $P_{i}$.
Definition 3.9 We say that a subset of states $C \subset S$ is a cluster, if, simultaneously,

$$
\min _{j \in C} P_{j}\left(\cap_{i \in C} G_{i}\right)>0, \quad \text { and } \quad P_{j}\left(\cap_{i \in C} G_{i}\right)=0 \quad \forall j \notin C
$$

Hence, a cluster is a maximal subset of states such that the corresponding emission distributions have a "detectable" intersection of their supports. The clusters are not necessarily disjoint and a cluster can consist of a single state. In this latter case the state is not hidden: Any emission from this state indicates that state. If $K=2$, then, for an HMM, there is only one cluster (otherwise the underlying Markov chain would not be hidden as all observations reveal their states). In many cases in practise there is only one cluster, that is $S$.
A proof of Lemma 3.1 below is given in the Appendix.
Lemma 3.1 Assume that for each state $l \in S$,

$$
\begin{equation*}
P_{l}\left(x: f_{l}(x) \max _{j}\left\{p_{j l}\right\}>\max _{i, i \neq l}\left\{f_{i}(x) \max _{j}\left\{p_{j i}\right\}\right\}\right)>0 . \tag{48}
\end{equation*}
$$

Moreover, assume that there exist a cluster $C \subset S$ and a finite integer $m<\infty$ such that the m-th power of the sub-stochastic matrix $Q=\left(p_{i j}\right)_{i, j \in C}$ has all of its entries non-zero. Then, for some integer $M$ and $r, M>r \geq 0$, there exists a set $\mathcal{Y}=\mathcal{Y}_{1} \times \cdots \times \mathcal{Y}_{M} \subset \mathcal{X}^{M}$, an $M$-tuple of states $q_{1 \ldots M} \in S^{M}$, and a state $l \in S$, such that every vector $y_{1 \ldots M} \in \mathcal{Y}$ is an $l$-barrier of order $r, q_{M-r}=l$ and

$$
\mathbf{P}\left(\left(X_{1}, \ldots, X_{M}\right) \in \mathcal{Y} \mid Y_{1}=q_{1}, \ldots, Y_{M}=q_{M}\right)>0, \quad \mathbf{P}\left(Y_{1}=q_{1}, \ldots, Y_{M}=q_{M}\right)>0
$$

Lemma 3.1 implies that $\mathbf{P}\left(\left(X_{1}, \ldots, X_{M}\right) \in \mathcal{Y}\right)>0$. Every element of $\mathcal{Y}$ is a ( $r$-order) barrier. By the ergodicity of $X$, a.e. realization of $X$ therefore has infinitely many $l$ barriers of order $r$, hence each such realization also has infinitely many $l$-nodes of order $r$.

### 3.4.1 Separated barriers

If we were to apply Corollary 3.4 to a realization with infinitely many $l$-nodes of order $r$, we would first need to ensure that $u_{i+1}>u_{i}+r$ for $i=1,2, \ldots$, where $u_{i}$ 's are the locations of the nodes. Obviously, one can easily select a subsequence of those nodes to enforce this condition. For some technical reasons related to the construction of the infinite alignment process (§4), we, however, choose first to define special barriers for which the above "separation" condition is always satisfied. Then, we give a formal statement (Lemma 3.2 below) guaranteeing that these separated barriers also occur infinitely often. Let $\mathcal{Y} \subset \mathcal{X}^{M}$ and $M$ and $r$ be as in Lemma 3.1 and $x_{j \ldots j+M-1} \in \mathcal{Y}$, i.e. is an $l$-barrier of order $r$ for some $l \in S$ and some $j>0$, and $x_{j+M-r-1}$ is an $l$-node of order $r$. However, it might happen that for some $i, j \leq i \leq j+r, x_{i \ldots i+M-1}$ is also in $\mathcal{Y}$. Then $x_{i+M-r-1}$ is another node of order $r$. In this case, $i+M-r-1-(j+M-r-1) \leq r$ and Corollary 3.4 can not be used (in the presence of ties) with these two nodes simultaneously.

Definition 3.10 Let $\mathcal{Y} \subset \mathcal{X}^{k}$ such that all its elements are l-barriers of order $r(r \leq k)$, and let $y_{1 \ldots k} \in \mathcal{Y}$. We say that $y_{1 \ldots k}$ is a separatedr ${ }^{\text {th }}$ order $l$-barrier relative to $\mathcal{Y}$ if for any $w, 1 \leq w \leq r$, and for any $y_{1 \ldots w}^{\prime} \in \mathcal{X}^{w}$ the concatenated block $\left(y_{1 \ldots w}^{\prime}, y_{1 \ldots k-w}\right) \notin \mathcal{Y}$.

In other words, a barrier is separated, if the distance from the previous barrier is at least $r+1$. Next, Lemma 3.2 (proven in Appendix) shows that a.e. realization of $X$ has infinitely many separated barriers.

Lemma 3.2 Suppose the assumptions of Lemma 3.1 are satisfied. Let $M, r, \mathcal{Y} \subset \mathcal{X}^{M}$ and $q_{1 \ldots M}$ be as promised by Lemma 3.1. Then, for some $N \geq M$, there exist a set $\mathcal{Y}^{*}=\mathcal{Y}_{1} \times \cdots \times \mathcal{Y}_{N-M} \times \mathcal{Y} \subset \mathcal{X}^{N}$, an $N$-tuple of states $q^{*}=\left(q_{1 \ldots N-M}^{*}, q_{1 \ldots M}\right) \in S^{N}$, and a state $l \in S$ such that every vector $y_{1 \ldots N} \in \mathcal{Y}^{*}$ is an l-barrier of order $r$, and moreover $y_{N-M+1 \ldots N} \in \mathcal{Y}$ is a separated $r^{\text {th }}$-order l-barrier relative to $\mathcal{Y}, q_{M-r}=l$ and

$$
\mathbf{P}\left(\left(X_{1}, \ldots, X_{N}\right) \in \mathcal{Y}^{*} \mid\left(Y_{1}, \ldots, Y_{N}\right)=q^{*}\right)>0, \quad \mathbf{P}\left(\left(Y_{1}, \ldots, Y_{N}\right)=q^{*}\right)>0
$$

### 3.4.2 Counterexamples

The condition on $C$ in Lemma 3.1 might seem technical and even unnecessary. We next give an example of an HMM where the cluster condition is not fulfilled and no barriers can occur. Then, we will modify the example (Examples 3.12 3.13) to enforce the cluster condition and consequently gain barriers.

Example 3.11 Let $K=4$ and consider an ergodic Markov chain with transition matrix

$$
P=\left(\begin{array}{cccc}
\frac{1}{2} & 0 & 0 & \frac{1}{2} \\
0 & \frac{1}{2} & \frac{1}{2} & 0 \\
\frac{1}{2} & 0 & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & 0 & \frac{1}{2}
\end{array}\right)
$$

Let the emission distributions be such that (48) is satisfied and $G_{1}=G_{2}$ and $G_{3}=G_{4}$ and $G_{1} \cap G_{3}=\emptyset$. Hence, in this case there are two disjoint clusters $C_{1}=\{1,2\}, C_{2}:=\{3,4\}$.

The matrices $Q_{i}$ corresponding to $C_{i}, i=1,2$ are

$$
Q_{1}=Q_{2}=\left(\begin{array}{cc}
\frac{1}{2} & 0 \\
0 & \frac{1}{2}
\end{array}\right)
$$

Evidently, the cluster assumption of Lemma 3.1 is not satisfied. Note also that the alignment cannot change (in one step) its state to the other one of the same cluster. Due to the disjoint supports, any observation indicates the corresponding cluster. Hence any sequence of observations can be regarded as a sequence of blocks emitted from alternating clusters. However, the alignment inside each block stays constant.

In order to see that no $x_{u}$ can be a node (of any order) for $1 \leq u<n$, recall $t(u, j)$ (17) and $t(u, j)^{(r)}(38)$, and Proposition 3.4. Specifically, note that in this setting for any $j \in S$ $t(u, j)$ contains exactly one element, hence for any $r \geq 1, t(u, j)^{(r)}$ defines a function from $S$ to $S$. Now, it is easy to see that depending on $x_{u}, t(u, j)$ belongs to a single cluster $C\left(x_{u}\right)$ for all $j \in S$. In particular, there are $i, j \in C^{\prime} \subset S$ for some cluster $C^{\prime}$ such that $i \neq j$. Given this particular transition matrix, evidently $t(u, i) \neq t(u, j)$. Hence, $x_{u}$ cannot be a (zero order) node (by (42)). Now, starting with $u+1$ (instead of u), the same argument establishes that for some $i, j \in S, t(u+1, i) \neq t(u+1, j)$ but are in one cluster. Applying the same argument again but now to $t(u+1, i)$ and $t(u+1, j)$, we get that $t(u, t(u+1, i)) \neq t(u, t(u+1, j))$, i.e. $t^{(2)}(u, i) \neq t^{(2)}(u, j)$. Consequently $x_{u}$ cannot be $a$ first order node (42); and so forth and so on recursively for any $r$ such that $0 \leq r<n-u$.

Example 3.12 Let us modify the HMM in Example 3.11 to ensure the assumptions of Lemma 3.1 hold. At first, let us change the transition matrix. Let $0<\epsilon<\frac{1}{2}$ and consider the Markov chain $Y$ with transition matrix

$$
\left(\begin{array}{cccc}
\frac{1}{2}-\epsilon & \epsilon & 0 & \frac{1}{2} \\
\epsilon & \frac{1}{2}-\epsilon & \frac{1}{2} & 0 \\
\frac{1}{2} & 0 & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & 0 & \frac{1}{2}
\end{array}\right) .
$$

Let the emission distributions be as in the previous example. In this case, the cluster $C_{1}$ satisfies the assumption of Lemma 3.1. As previously, every observation indicates its cluster. Unlike in the previous example, nodes are now possible. To be concrete, let $\epsilon=1 / 4, f_{1}(x)=\exp (-x)_{x \geq 0}, f_{2}(x)=2 \exp (-2 x)_{x \geq 0}$, and $f_{3}(x)=\exp (x)_{x \leq 0}, f_{4}(x)=$ $2 \exp (2 x)_{x \leq 0}$. It can then be verified that, for example, if $x_{1}=1, x_{2}=1$ then $x_{1}$ is a 1 -node of order 2. Indeed, in that case any element of $\mathcal{Y}=(0,+\infty) \times(\log (2),+\infty) \times(0,+\infty)$ is a 1-barrier of order 2.

Example 3.13 Another way to modify the HMM in Example 3.11 to enforce the assumptions of Lemma 3.1 is to change the emission probabilities. Assume that the supports $G_{i}$, $i=1, \ldots, 4$ are such that $P_{j}\left(\cap_{i=1}^{4} G_{i}\right)>0$ for all $j \in S$, and (48) holds. Now, the model has only one cluster that is $S=\{1, \ldots, 4\}$. Since the matrix $P^{2}$ has all its entries positive, the conditions of Lemma 3.1 are now satisfied. A barrier can now be constructed. For example, the following block of observations,

$$
\begin{equation*}
z_{1}, z_{2}, z_{3}, y_{1}, \ldots, y_{k}, z_{1}^{\prime}, z_{2}^{\prime}, z_{3}^{\prime} \tag{49}
\end{equation*}
$$

where $z_{i}, z_{i}^{\prime} \in \cap_{j=1}^{4} G_{j}, i=1,2,3, y_{i} \in \mathcal{X}, i=1, \ldots k$ and $k$ is sufficiently large, is a barrier (see proof of Lemma 3.1). The construction of barriers in this case is possible because of the observations $z_{i}$ and $z_{i}^{\prime}$. These observations can be emitted from any state (i.e. from any distribution $P_{i}, i=1, \ldots, 4$ ) and therefore do not indicate any proper subsets of $S$. They play a role of a buffer allowing a change in the alignment from a given state to any other state (in 3 steps). The HMM in Example 3.11 does not have r-order nodes, because such buffers do not arise. The cluster assumption in Lemma 3.1 makes these buffers possible.

## 4 Alignment process

Let $x_{1 \infty}=x_{1}, x_{2}, \ldots$ be a realization of $X$. If for some $r<\infty x_{1 \infty}$ contains infinitely many $r$-order nodes, then Corollary 3.4 paves the way for defining an infinite alignment for $x_{1 \infty}$.

### 4.1 Preliminaries

Throughout this Section, we work under the assumptions of Lemma 3.1. Let $M \geq 0$, $\mathcal{Y} \subset \mathcal{X}^{M}, r \geq 0$, and $l \in S$ as promised by Lemma 3.1. Then, by Lemma 3.2, for some $N>r \geq 0$, there exist $\mathcal{Y}^{*}=\mathcal{Y}^{\prime} \times \mathcal{Y} \subset \mathcal{X}^{N}$ for some $\mathcal{Y}^{\prime} \subset \mathcal{X}^{N-M}$, and an $N$-tuple of states $q^{*}=q_{1 \ldots N} \in S^{N}$ such that for every $n$,
$\mathbf{P}\left(\left(Y_{n}, \ldots, Y_{n+N-1}\right)=q^{*}\right)>0, \quad \mathbf{P}\left(\left(X_{n}, \ldots, X_{n+N-1}\right) \in \mathcal{Y}^{*} \mid\left(Y_{n}, \ldots, Y_{n+N-1}\right)=q^{*}\right)>0$
hence every $x_{n \ldots n+N-1} \in \mathcal{Y}^{*}$ is (ends with) a separated barrier from $\mathcal{Y}$.
Denote $\mathbf{P}\left(\left(X_{n}, \ldots, X_{n+N-1}\right) \in \mathcal{Y}^{*}\right)$ by $\gamma^{*}$, thus $\gamma^{*}>0$, and define

$$
\begin{equation*}
U_{n}=\left(X_{n}, \ldots, X_{n+N-1}\right), \quad D_{n}=\left(Y_{n}, \ldots, Y_{n+N-1}\right) \tag{50}
\end{equation*}
$$

Let $\mathcal{F}_{n}:=\sigma\left(Y_{1}, \ldots, Y_{n}, X_{1}, \ldots, X_{n}\right)$. Define stopping times $\nu_{o}, \nu_{1}, \nu_{2}, \ldots, R_{0}, R_{1}, R_{2}, \ldots$, and $\vartheta_{0}, \vartheta_{1}, \vartheta_{2}, \ldots$, of the filtration $\left\{\mathcal{F}_{n+N-1}\right\}_{n=1}^{\infty}$ as follows:

$$
\begin{align*}
& \nu_{o}:=\min \left\{n \geq 1: U_{n} \in \mathcal{Y}^{*}, D_{n}=q^{*}\right\}, \quad \nu_{i}:=\min \left\{n>\nu_{i-1}: U_{n} \in \mathcal{Y}^{*}, D_{n}=q^{*}\right\}  \tag{51}\\
& \vartheta_{o}:=\min \left\{n \geq 1: U_{n} \in \mathcal{Y}^{*}\right\}, \quad \vartheta_{i}:=\min \left\{n>\vartheta_{i-1}: U_{n} \in \mathcal{Y}^{*}\right\}  \tag{52}\\
& R_{0}:=\min \left\{n \geq 1: D_{n}=q^{*}\right\}, \quad R_{i}:=\min \left\{n>R_{i-1}: D_{n}=q^{*}\right\} . \tag{53}
\end{align*}
$$

We use the convention $\min \emptyset=0$ and $\max \emptyset=-1$. Note the difference between $\nu$ and $R$ and $\vartheta$ : The stopping times $\vartheta$ are observable by looking at the $X$ process only; the stopping times $R$ are observable by looking at the $Y$ process only; the sopping times $\nu$ require the knowledge of the full two-dimensional process $(X, Y)$. Clearly $\vartheta_{i} \leq \nu_{i}$, and $R_{i} \leq \nu_{i}$.

From (53), it follows that the random variables $R_{0},\left(R_{1}-R_{0}\right),\left(R_{2}-R_{1}\right), \ldots$ are independent and $\left(R_{1}-R_{0}\right),\left(R_{2}-R_{1}\right), \ldots$ are identically distributed. The same evidently holds for the random variables $\nu_{0},\left(\nu_{1}-\nu_{0}\right),\left(\nu_{2}-\nu_{1}\right), \ldots$ In Appendix, we prove that all the latter ones have finite expectations, and, therefore, are stationary renewal times:

Proposition 4.1 $E\left(\nu_{1}-\nu_{0}\right)<\infty$ and for any $\pi^{\prime}$ (not necessarily equal to $\pi$, the invariant distribution) initial distribution of $Y, E_{\pi^{\prime}} \nu_{0}<\infty$.

To every $\nu_{i}, \quad i=0,1, \ldots$ there corresponds an $r$-order $l$-barrier. This barrier occupies the interval $\left[\nu_{i}+N-M, \nu_{i}+N-1\right]$. By Definition 3.8, $X_{\tau_{i}}$ is an $l$-node of order $r$, where

$$
\tau_{i}=\nu_{i}+(N-1)-r, \quad i=0,1, \ldots
$$

Define

$$
\begin{equation*}
T_{0} \stackrel{\text { def }}{=} \tau_{0}, \quad T_{i} \stackrel{\text { def }}{=} \tau_{i}-\tau_{i-1}=\left(\nu_{i}-\nu_{i-1}\right), i=1,2, \ldots \tag{54}
\end{equation*}
$$

From Proposition 4.1, it immediately follows $E_{\pi^{\prime}} T_{1}<\infty, E_{\pi^{\prime}} T_{0}<\infty$, where $\pi^{\prime}$ is any initial distribution of $Y$. Thus $T_{i}, i=0,1, \ldots$ correspond to a delayed renewal process [6].

Let $u_{0}, u_{1}, u_{2}, \ldots$ be the locations of the $r$-order $l$-nodes corresponding to the stopping times $\vartheta$, i.e.

$$
\begin{equation*}
u_{i}=\vartheta_{i}+(N-1)-r, \quad i=0,1,2, \ldots \tag{55}
\end{equation*}
$$

Clearly, every $\tau_{i}$ is also a $u_{j}$ for some $j \geq i$. Also, since the barriers are separable, $u_{i}>u_{i-1}+r$.

### 4.2 Alignments

We next specify the alignments $v\left(x_{1 \ldots n}\right) \in \mathcal{V}\left(x_{1 \ldots n}\right)$, and define $v\left(x_{1 \ldots \infty}\right)$ and the measures $P_{l}^{n}$ corresponding to $v\left(x_{1 \ldots n}\right)$.

Let $k\left(x_{1 \ldots n}\right)$ be the number of $x_{u_{0}}, x_{u_{1}}, \ldots, x_{u_{k\left(x_{1} \ldots n\right)-1}}$, all $l$ nodes of order $r$ such that $u_{i}>u_{i-1}+r$ for $i=1, \ldots, k\left(x_{1 \ldots n}\right)-1$, and $u_{k\left(x_{1 \ldots n)-1}\right.}+r<n$. Recall (Definition 3.7) that based on the selection $\vee$ (33), we single out the following proper piecewise alignment:

$$
\begin{aligned}
v\left(x_{1 \ldots n}\right)= & \left(\vee \mathcal{W}_{u_{0}}^{l}\left(x_{1 \ldots u_{0}}\right), \vee \mathcal{W}_{(l) u_{1}}^{l}\left(x_{u_{0}+1 \ldots u_{1}}\right), \ldots,\right. \\
& \left.\vee \mathcal{W}_{(l) u_{k-1}}^{l}\left(x_{u_{k-2}+1 \ldots u_{k-1}}\right), \vee \mathcal{V}_{(l)}\left(x_{u_{k-1}+1 \ldots n}\right)\right) \in \mathcal{V}_{u_{0} \ldots u_{k-1}}^{l \ldots l}\left(x_{1 \ldots n}\right),
\end{aligned}
$$

for $k=k\left(x_{1 \ldots n}\right)>0$, and $v\left(x_{1 \ldots n}\right)=\vee \mathcal{V}\left(x_{1 \ldots n}\right)$ for $k=0$. Corollary 3.4 makes it possible to define the infinite proper piecewise alignment that will be consistent with Definition 3.7 (in the sense of (56) below). Namely, we state

## Definition 4.1

$$
v\left(x_{1 \ldots \infty}\right) \stackrel{\text { def }}{=}\left(\vee \mathcal{W}_{u_{0}}^{l}\left(x_{1 \ldots u_{0}}\right), \vee \mathcal{W}_{(l) u_{1}}^{l}\left(x_{u_{0}+1 \ldots u_{1}}\right), \ldots,\right)
$$

for all $x_{1 \infty}$ that contain infinitely many $x_{u_{0}}, x_{u_{1}}, \ldots, l$-nodes of order $r$, which is the case a.s. (Lemmas 3.1 and 3.2). (For all other realizations, let us adopt $v\left(x_{1 \ldots \infty}\right) \stackrel{\text { def }}{=}$ $\left(\vee \mathcal{W}_{u_{0}}^{l}\left(x_{1 \ldots u_{0}}\right), \vee \mathcal{W}_{(l) u_{1}}^{l}\left(x_{u_{0}+1 \ldots u_{1}}\right), \ldots, \vee \mathcal{W}_{(l) u_{k-1}}^{l}\left(x_{u_{k-2}+1 \ldots u_{k-1}}\right), 1,1, \ldots\right)$, where $k$ is the total number of $l$ nodes of order $r$ in the given realization.)
Note that for every $x_{u_{i}}$ observed in $\left(x_{1}, \ldots, x_{n}\right)$

$$
\begin{equation*}
v\left(x_{1}^{\infty}\right)_{1 \cdots u_{i}}=v\left(x_{1}, \ldots, x_{n}\right)_{1 \cdots u_{i}} . \tag{56}
\end{equation*}
$$

Let us now formally define the empirical measures $P_{l}^{n}$ which are central to this theory:
Definition 4.2 Let $=V_{1 \ldots n}^{\prime}=v\left(X_{1}, \ldots, X_{n}\right)$ (where $v$ is as in Definition 3.7). For each state $l \in S$ that appears in $V_{1}^{\prime}, V_{2}^{\prime}, \ldots V_{n}^{\prime}$ define the empirical l-measure

$$
P_{l}^{n}\left(A, X_{1 \ldots n}\right) \stackrel{\text { def }}{=} \frac{\sum_{i=1}^{n} I_{A \times l}\left(X_{i}, V_{i}^{\prime}\right)}{\sum_{i=1}^{n} I_{l}\left(V_{i}^{\prime}\right)}, \quad A \in \mathcal{B} .
$$

For other $l \in S$ (i.e. such that $l \neq V_{i}^{\prime}$ for $i=1, \ldots, n$ ), define $P_{l}^{n}$ to equal some arbitrarily chosen (probability) measure $P^{*}$.

The infinite alignment allows us to define the alignment process:
Definition 4.3 The encoded process $V \stackrel{\text { def }}{=} v(X)$ will be called the alignment process.
(Of course, the definition of $V$ above is sensible only because $X$ has infinitely many $u_{i}$-s a.s..) We shall also consider the 2-dimensional process

$$
Z \stackrel{\text { def }}{=}(X, V)
$$

Using $Z$, we define a related quantity $Q_{l}^{n}$ as follows: Let $V_{1}, \ldots, V_{n}$ be the first $n$ elements of the alignment process. In general

$$
v\left(x_{1}^{\infty}\right)_{1 \ldots n} \neq v\left(x_{1}, \ldots, x_{n}\right)
$$

hence $V_{i}^{\prime}$ need not equal $V_{i}$. For every $l \in S$, we define

$$
Q_{l}^{n}\left(A, Z_{1 \ldots n}\right) \stackrel{\text { def }}{=} \frac{\sum_{i=1}^{n} I_{A \times l}\left(X_{i}, V_{i}\right)}{\sum_{i=1}^{n} I_{l}\left(V_{i}\right)}=\frac{\sum_{i=1}^{n} I_{A \times l}\left(Z_{i}\right)}{\sum_{i=1}^{n} I_{l}(V)}, \quad A \in \mathcal{B} .
$$

(As in Definition 4.2, if $l \neq V_{i}, i=1, \ldots, n$, then $Q_{l}^{n} \stackrel{\text { def }}{=} P^{*}$.)

### 4.3 Regenerativity

To prove our main theorem, we use the fact that $Z$ is a regenaritive process:
Proposition 4.2 The processes $V, X$, and $Z$ are regenerative with respect to $\tau$.
The proof is given in the Appendix.
Recall $\mathcal{Y}^{*}=\mathcal{Y}_{1} \times \cdots \times \mathcal{Y}_{N-M} \times \mathcal{Y}_{N-M+1} \times \cdots \times \mathcal{Y}_{N}$ and $q^{*}=q_{1 \ldots N}$ (from §4.1), and let

$$
P_{q_{i}}^{r} \propto P_{q_{i}} I_{\mathcal{Y}_{i}}, \quad i=1, \ldots, N .
$$

Thus, $P_{q_{i}}^{r}$ is the measure $P_{q_{i}}^{r}$ conditioned on $\mathcal{Y}_{i}$. Recall also that $q_{N-r}=l$.
Define new processes

$$
\begin{equation*}
Y^{r} \stackrel{\text { def }}{=}\left(Y_{i}^{r}\right)_{i=1}^{\infty}, \quad \text { where } \quad Y_{1}^{r}=q_{N-r+1}, \ldots, Y_{r}^{r}=q_{N}, \quad \text { and } \quad Y_{r+1}^{r}, Y_{r+2}^{r}, \ldots \tag{57}
\end{equation*}
$$

is an $S$-valued Markov chain with transition probability matrix $P$ and initial distribution $\left(p_{q_{N} j}\right)_{j \in S}$;
$X^{r} \stackrel{\text { def }}{=}\left(X_{i}^{r}\right)_{i=1}^{\infty}$ is a modified HMM with $Y^{r}$ as its underlying Markov chain and
$P_{Y_{i}^{r}}(i>r)$ and $P_{q_{N-r+i}}^{r}(1 \leq i \leq r)$ as its emission distributions;
$V^{r} \stackrel{\text { def }}{=}\left(V_{i}^{r}\right)_{i=1}^{\infty} \stackrel{\text { def }}{=} v\left(X^{r}\right)$, where $v$ is as in Definition 4.1;

$$
\begin{equation*}
Z^{r} \stackrel{\text { def }}{=}\left(X^{r}, V^{r}\right) \tag{59}
\end{equation*}
$$

Note that the process $X^{r}$ is not exactly an HMM as defined in Definition 2.1 because the first $r$-emissions are generated from distributions that differ from the distributions of the rest. However, conditioned on the underlying Markov Chain $Y^{r}$, all emissions are still independent. Also note that in the definition of $V^{r}$, the alignment is still based on the original HMM $X$, i.e. the definition of $v\left(x_{1}, \ldots, x_{n}\right)$ relies on the distributions $P_{q_{1}}$, $P_{q_{2}}, \ldots, P_{q_{n}}$ (given $Y_{1 \ldots n}=q_{1 \ldots n}$ ).

Finally, note that for $r=0$, the process $Y^{0}$ is essentially our original Markov chain except fro the initial distribution being $\left(p_{l j}\right)_{j \in S}$ (instead of $\pi$ ). Similarly, $X^{0}$ is the HMM in the sense of Definition 2.1 with $Y^{0}$ as its underlying Markov chain. Therefore, $Z^{0}$ is the process $Z$, with $\left(p_{l j}\right)_{j \in S}$ as the initial distribution of its $Y$-component.

Finally we define analogues of $\nu_{0}$ and $\tau_{0}$ :

$$
\begin{align*}
& \left.\nu_{0}^{r} \stackrel{\text { def }}{=} \min \left\{n \geq 1:\left(Y_{n}^{r}, \ldots, Y_{n+N-1}^{r}\right)=q^{*}, \quad\left(X_{n}^{r}, \ldots, X_{n+N-1}^{r}\right) \in \mathcal{Y}^{*}\right)\right\} \\
& \tau_{0}^{r} \stackrel{\text { def }}{=} \nu_{0}^{r}+(N-1)-r . \tag{60}
\end{align*}
$$

Note that the random variable $\tau_{0}^{r}$ has the same law as $T_{i}(54), i \geq 1$. The barriers in $\mathcal{Y}^{*}$ end by (length $M$ ) $l$ barriers of order $r$ from $\mathcal{Y}=\mathcal{Y}_{N-M+1} \times \mathcal{Y}_{N-M+2} \times \cdots \times \mathcal{Y}_{N}$ that are separated relative to $\mathcal{Y}$ (Definition 3.10, Lemma 3.2). Therefore, $\nu_{0}^{r}>r$. This means that the laws of $\nu_{0}^{r}, \tau_{0}^{r}, \nu_{0}+r$, and $\tau_{0}+r$ would all be equal if $Y$ had $\left(p_{q_{M} l}\right)_{l \in S}$ for the initial distribution. Recalling that any initial distribution $\pi$ of $Y$ yields $E_{\pi}\left(\nu_{0}\right)<\infty$ (Proposition 4.1), we obtain

$$
\begin{equation*}
E T_{1}=E \tau_{0}^{r}=E_{q_{M}}\left(\nu_{0}+(N-1)-r+r\right)<\infty . \tag{61}
\end{equation*}
$$

The above observations will allow us to prove (see Appendix) the following theorem which is the main result of the paper:
Theorem 4.4 If $X$ satisfies the assumptions of Lemma 3.1, then there exist probability measures $Q_{l}, l \in S$ such that

$$
P_{l}^{n} \Rightarrow Q_{l}, \quad \text { a.s., } \quad Q_{l}^{n} \Rightarrow Q_{l}, \quad \text { a.s. }
$$

and for each $A \in \mathcal{B}$,

$$
\begin{equation*}
Q_{l}(A)=\frac{\sum_{i=1}^{\infty} \mathbf{P}\left(Z_{i}^{r} \in A \times l, \tau_{o}^{r} \geq i\right)}{\sum_{i=1}^{\infty} \mathbf{P}\left(V_{i}^{r}=l, \tau_{o}^{r} \geq i\right)} \tag{62}
\end{equation*}
$$

where $V^{r}, Z^{r}$, and $\tau_{o}^{r}$ are defined in (58), (59), and (60), respectively.
Corollary 4.1 Suppose $X$ satisfies the assumptions of Lemma 3.1 with $r=0$. Then, for each $l \in S$ (62) takes form

$$
\begin{equation*}
Q_{l}(A)=\frac{\sum_{j=1}^{\infty} \mathbf{P}_{l}\left(Z_{j} \in A \times i, \tau_{o} \geq j\right)}{\sum_{j=1}^{\infty} \mathbf{P}_{l}\left(V_{j}=i, \tau_{o} \geq j\right)} \tag{63}
\end{equation*}
$$

where $P_{l}$ stands for initial distribution of $Y$ equal $\left(p_{l j}\right)_{j \in S}$.

## 5 Appendix

### 5.1 Proof of Lemma 3.1

Work in progress.

### 5.2 Proof of Lemma 3.2

Work in progress.

### 5.3 Proof of Proposition 4.1

We define blocked processes

$$
U_{m}^{b}=\left(X_{(m-1) N+1}, \ldots, X_{m N}\right), \quad D_{m}^{b}=\left(Y_{(m-1) N+1}, \ldots, Y_{m N}\right), \quad m=1,2, \ldots
$$

and stopping times

$$
\begin{align*}
\nu_{o}^{b} & :=\min \left\{m \geq 1: U_{m}^{b} \in \mathcal{Y}^{*}, D_{m}^{b}=Q^{*}\right\}  \tag{64}\\
\nu_{i}^{b} & :=\min \left\{m>\nu_{i-1}^{*}: U_{m}^{b} \in \mathcal{Y}^{*}, D_{m}^{b}=Q^{*}\right\} \\
&  \tag{65}\\
R_{0}^{b} & :=\min \left\{m>1: D_{m}^{b}=Q^{*}\right\} \\
R_{i}^{b} & :=\min \left\{m>R_{i-1}: D_{m}^{*}=Q^{*}\right\}
\end{align*}
$$

The process $D^{b}$ is a finite MC, since $Y$ is non-periodic and irreducible, the same holds for $D^{b}$. Hence ( $D^{b}, U^{b}$ ) is a HMM.
Since $Y$ is stationary, $Q^{*}$ occurs in every possible integer-interval with the same probability; so $Q^{*}$ belongs to the state space of $D^{b}$. Since $D^{b}$ is irreducible and finite, then every state is visited infinitely often, a.s. This means that for every $i=1,2, \ldots$, $\mathbf{P}\left(R_{i}^{b}-R_{i-1}^{b}<\infty\right)=1$ and then, of course, $\mathbf{P}\left(R_{i}-R_{i-1}<\infty\right)=1$.
If $D_{m}^{b}=Q^{*}$, then by Lemma 3.2, $U_{m}^{b} \in \mathcal{Y}^{*}$ with probability $\gamma^{*}>0$. This means that for every $i=1,2, \ldots, \mathbf{P}\left(\nu_{i}^{b}-\nu_{i-1}^{b}<\infty\right)=1$ and this means $\mathbf{P}\left(\nu_{i}-\nu_{i-1}<\infty\right)=1$.
The chain $D^{b}$ has finite state space and is ergodic. Hence, for any initial distribution of $D^{*}$, we have $E\left(R_{0}\right) \leq N E\left(R_{0}^{b}\right)<\infty$. Every initial distribution $\pi$ of $Y$ induces an initial distribution of $D^{b}$. Thus, for any $\pi, E_{\pi}\left(R_{0}\right)<\infty$. Now, obviously, $E \nu_{0}=\gamma^{*-1} E_{\pi}\left(R_{0}\right)<\infty$. This proves the second statement.

To prove the first statement, consider the blocked Markov chain $D^{b}$ with initial distribution concentrated on $Q^{*}$. The fact that $E\left(R_{0}\right) \leq N E\left(R_{0}^{b}\right)<\infty$ with any initial distribution implies that $E\left(R_{1}-R_{0}\right)<\infty$ and, hence, $E\left(\nu_{1}-\nu_{0}\right)=\left(\gamma^{*}\right)^{-1} E\left(R_{1}-R_{0}\right)<\infty$.

### 5.4 Proof of Proposition 4.2

Recall the definition of stopping times $\tau$. By definition, for each $i$ the underlying Markov chain satisfies $Y_{\tau_{i}}=l$. Hence, the behavior of $X$ after $\tau_{i}$ does not depend of the behavior of $X$ up to $\tau_{i}$. With the fact that $T_{i}$ are renewal, this establishes the regenerativity of
$X$. To every $\tau_{i}$ corresponds a $r$-order $l$-node. Moreover, since $\tau_{i}$ is always a $u_{j}$, for some $j>i$, it means that all the nodes corresponding to $\tau_{i}$-s are also used to fix the alignment in Definition 4.1. Therefore, the alignment up to $\tau_{i}$ does not depend on the alignment after $\tau_{i}$. In other words, the piece of alignment process corresponding to the $T_{i}$ is a function of the piece of $X$ corresponding to the $T_{i}$. Formally

$$
\left(V_{s}: s \in \tau_{i-1}+1, \ldots, \tau_{i}\right)=v_{(l)}\left(X_{s}: s \in \tau_{i-1}+1, \ldots, \tau_{i}\right)
$$

So, the process $Z$ is regenerative with respect to $\tau$.

### 5.5 Proof of Theorem 4.4

At first note that the right side of (62) defines a measure.
The proof uses the regenerativity of $Z$ in the most standard way. For every $n \geq \tau_{o}$ and $A \in \mathcal{B}$, and for every $l \in S$.

$$
\frac{1}{n} \sum_{i=1}^{n} I_{A \times l}\left(Z_{i}\right)=\frac{1}{n} \sum_{i=1}^{\tau_{o}} I_{A \times l}\left(Z_{i}\right)+\frac{1}{n} \sum_{i=\tau_{o}+1}^{\tau_{k(n)}} I_{A \times l}\left(Z_{i}\right)+\frac{1}{n} \sum_{i=\tau_{k(n)}+1}^{n} I_{A \times l}\left(Z_{i}\right)
$$

where $k(n)=\max \left\{k: \tau_{k} \leq n\right\}$ stands for the renewal process. Now, since $\tau_{o}<\infty$, a.s., we have

$$
\frac{1}{n} \sum_{i=1}^{\tau_{o}} I_{A \times l}\left(Z_{i}\right) \leq \frac{\tau_{o}}{n} \rightarrow 0, \quad \text { a.s.. }
$$

Let $\mu:=E \tau_{0}^{r}$. By (61), $\mu<\infty$. Then

$$
\frac{n-\tau_{k(n)}}{n} \leq \frac{T_{k(n)+1}}{n} \rightarrow 0, \quad \text { a.s.. }
$$

Finally, since $Z$ is a regenerative process with respect to the $\tau_{o}, \tau_{1}, \ldots$, we have

$$
\frac{1}{n} \sum_{i=\tau_{o}+1}^{\tau_{k(n)}} I_{A \times l}\left(Z_{i}\right)=\frac{k(n)}{n} \frac{1}{k(n)} \sum_{k=1}^{k(n)} \xi_{k}
$$

where

$$
\xi_{k}:=\sum_{i=\tau_{k-1}+1}^{\tau_{k}} I_{A \times l}\left(Z_{i}\right), \quad k=1,2, \ldots
$$

are i.i.d. random variables. Denote $m_{l}(A):=E \xi_{k} \leq \mu<\infty$ (and drop the $A$, because it is fixed). Then, as $n \rightarrow \infty$, we have

$$
\frac{n}{k(n)} \rightarrow \mu \quad \text { and } \quad \frac{1}{k(n)} \sum_{k=1}^{k(n)} \xi_{k} \rightarrow m_{l}, \quad \text { a.s. }
$$

Let us calculate $m_{l}$. Clearly,

$$
m_{l}=E \sum_{i=1}^{\tau_{0}^{r}} I_{A \times l}\left(Z_{i}^{r}\right)
$$

Now

$$
\begin{aligned}
m_{l} & =E \sum_{i=1}^{\tau_{0}^{r}} I_{A \times l}\left(Z_{i}^{r}\right)=\sum_{j=1}^{\infty} E\left(\sum_{i=1}^{j} I_{A \times l}\left(Z_{i}^{r}\right) \mid \tau_{0}^{r}=j\right) \mathbf{P}\left(\tau_{0}^{r}=j\right) \\
& =\sum_{j=1}^{\infty} \sum_{i=1}^{j} \mathbf{P}\left(Z_{i}^{r} \in A \times l \mid \tau_{0}^{r}=j\right) \mathbf{P}\left(\tau_{0}^{r}=j\right) \\
& =\sum_{j=1}^{\infty} \mathbf{P}\left(Z_{1}^{r} \in A \times l \mid \tau_{0}^{r}=j\right) \mathbf{P}\left(\tau_{0}^{r}=j\right)+\sum_{j=2}^{\infty} \mathbf{P}\left(Z_{2}^{r} \in A \times l \mid \tau_{0}^{r}=j\right) \mathbf{P}\left(\tau_{0}^{r}=j\right)+\cdots \\
& =\mathbf{P}\left(Z_{1}^{r} \in A \times l, \tau_{0}^{r} \geq 1\right)+\mathbf{P}\left(Z_{2}^{r} \in A \times l, \tau_{0}^{r} \geq 2\right)+\cdots \\
& =\sum_{i=1}^{\infty} \mathbf{P}\left(Z_{i}^{r} \in A \times l, \tau_{0}^{r} \geq i\right) \leq \sum_{i=1}^{\infty} \mathbf{P}\left(\tau_{0}^{r} \geq i\right)=\mu<\infty
\end{aligned}
$$

Similarly,

$$
\begin{equation*}
\frac{1}{n} \sum_{i=1}^{n} I_{l}\left(V_{i}^{r}\right) \rightarrow \frac{1}{\mu} \sum_{i=1}^{\infty} P\left(V_{i}^{r}=l, \tau_{0}^{r} \geq i\right)=: \frac{w_{l}}{\mu} \leq 1, \quad \text { a.s. } \tag{66}
\end{equation*}
$$

Hence, we have shown that for each $l \in S$ and for every $A \in \mathcal{B}$

$$
\begin{equation*}
Q_{l}^{n}(A) \rightarrow \frac{m_{l}(A)}{w_{l}}=\frac{\sum_{i=1}^{\infty} \mathbf{P}\left(Z_{i}^{r} \in A \times l, \tau_{0}^{r} \geq i\right)}{\sum_{i=1}^{\infty} \mathbf{P}\left(V_{i}^{r}=l, \tau_{0}^{r} \geq i\right)}, \quad \text { a.s. } \tag{67}
\end{equation*}
$$

The theory of weak convergence of measures (recall $\mathcal{X}$ was assumed to be a separable metric space) now establishes $Q_{l}^{n} \Rightarrow Q_{l}$, a.s..

It remains to show that, for all $l \in S$ and $A \in \mathcal{B}$

$$
\begin{equation*}
P_{l}^{n}(A) \rightarrow \frac{m_{l}(A)}{w_{l}}, \quad \text { a.s.. } \tag{68}
\end{equation*}
$$

For this consider the sum $\sum_{i=1}^{n} I_{A \times l}\left(X_{i}, V_{i}^{\prime}\right)$. Since $V_{i}^{\prime}=V_{i}$, if $i \leq \tau_{k(n)}$, we get, as $n \rightarrow \infty$

$$
\frac{1}{n} \sum_{i=1}^{n} I_{A \times l}\left(X_{i}, V_{i}^{\prime}\right)=\frac{1}{n} \sum_{i=1}^{\tau_{o}} I_{A \times l}(Z)+\frac{1}{n} \sum_{i=\tau_{o}+1}^{\tau_{k(n)}} I_{A \times l}\left(Z_{i}\right)+\frac{1}{n} \sum_{i=\tau_{k(n)}+1}^{n} I_{A \times l}\left(X_{i}, V_{i}^{\prime}\right) \rightarrow \frac{m_{l}}{\mu} \quad \text { a.s. }
$$

Similarly,

$$
\begin{equation*}
\frac{1}{n} \sum_{i=1}^{n} I_{l}\left(V_{i}^{\prime}\right) \rightarrow \frac{1}{\mu} \sum_{i=1}^{\infty} P_{1}\left(V_{i}=l, \tau_{0}^{r} \geq i\right)=: \frac{w_{l}}{\mu}, \quad \text { a.s.. } \tag{69}
\end{equation*}
$$

These convergences prove (68).
