HYPERCUBE PERCOLATION

REMCO VAN DER HOFSTAD AND ASAF NACHMIAS

ABSTRACT. We study bond percolation on the Hamming hypercube $\{0, 1\}^m$ around the critical probability p_c . It is known that if $p = p_c(1 + O(2^{-m/3}))$, then with high probability the largest connected component \mathcal{C}_1 is of size $\Theta(2^{2m/3})$ and that this quantity is non-concentrated. Here we show that for any sequence ε_m such that $\varepsilon_m = o(1)$ but $\varepsilon_m \gg 2^{-m/3}$ percolation on the hypercube at $p_c(1 + \varepsilon_m)$ has

$$|\mathcal{C}_1| = (2 + o(1))\varepsilon_m 2^m \quad \text{and} \quad |\mathcal{C}_2| = o(\varepsilon_m 2^m),$$

with high probability, where \mathcal{C}_2 is the second largest component. This resolves a conjecture of Borgs, Chayes, the first author, Slade and Spencer [18].

1. INTRODUCTION

Percolation on the Hamming hypercube $\{0, 1\}^m$ is a combinatorial model proposed in 1979 by Erdős and Spencer [24]. The study of its phase transition poses two inherent difficulties. Firstly, its non-trivial geometry makes the combinatorial “subgraph count” techniques unavailable. Secondly, the critical probability where the phase transition occurs is significantly larger than $1/(m-1)$, making the method of stochastic domination by branching processes very limited. Unfortunately, these are the two prominent techniques for obtaining scaling windows in mean-field settings (see e.g., [4, 13, 19, 23, 31, 37, 43, 45, 46, 47]).

In light of the second difficulty, Borgs, Chayes, the first author, Slade and Spencer [16, 17, 18] suggested that the precise location p_c of the phase transition is the unique solution to the equation

$$\mathbb{E}_{p_c} |\mathcal{C}(0)| = \lambda 2^{m/3}. \quad (1.1)$$

where $\mathcal{C}(0)$ is the connected component containing the origin, $|\mathcal{C}(0)|$ denotes its size, and $\lambda \in (0, 1)$ denotes an arbitrary constant. Later it will become clear how λ is chosen. The lace expansion was then employed by the authors to show that at $p = p_c(1 + O(2^{-m/3}))$ the largest connected component \mathcal{C}_1 is of size $\Theta(2^{2m/3})$ whp — the same asymptotics as in the critical Erdős and Rényi random graph both with respect to the size of the cluster and the width of the scaling window (see Section 1.1 for more details). However, this result does not rule out the possibility that this critical behavior proceeds beyond the $O(2^{-m/3})$ window and does not give an upper bound on the width of the scaling window.

The authors conjectured that the giant component “emerges” just above this window (see [18, Conjecture 3.2]). They were unable to prove this primarily because their combination of lace expansion and sprinkling methodology breaks for p above the scaling window. In this paper we resolve their conjecture:

Theorem 1.1. *Consider bond percolation on the Hamming hypercube $\{0, 1\}^m$ with $p = p_c(1 + \varepsilon)$, where $p_c = p_c(\lambda)$ with $\lambda \in (0, \infty)$ a fixed constant, and $\varepsilon = \varepsilon_m = o(1)$ is a positive sequence with $\varepsilon_m \gg 2^{-m/3}$. Then*

$$\frac{|\mathcal{C}_1|}{2\varepsilon_m 2^m} \xrightarrow{\mathbb{P}} 1,$$

where $\xrightarrow{\mathbb{P}}$ denotes convergence in probability, and

$$\mathbb{E}|\mathcal{C}(0)| = (4 + o(1))\varepsilon_m^2 2^m.$$

Furthermore, the second largest component \mathcal{C}_2 satisfies

$$\frac{|\mathcal{C}_2|}{\varepsilon_m 2^m} \xrightarrow{\mathbb{P}} 0.$$

The main novelty of our approach is showing that large percolation clusters behave in some sense like uniform random sets. We use this to deduce that two large clusters tend to “clump” together and form a giant component. This analysis replaces the appeal to the hypercube’s isoperimetric inequality which is key in all the previous works on this problem (see further details in Section 1.3). It essentially rules out the possibility that two large percolation clusters are “worst-case” sets, that is, sets which saturate the isoperimetric inequality (e.g., two balls of radius $m/2 - \sqrt{m}$ around the two poles of the hypercube). The precise behavior of the random walk on the hypercube plays a key role in proving such statements. Our proof combines this idea with some combinatorial ideas (the “sprinkling” method of [3], see Section 1.3), and ideas originating in statistical physics (Aizenman and Barsky’s [1] differential inequalities and variants of the triangle condition). Our proof methods are general and apply for other families of graphs such as various expanders of high degree and high girth, finite tori of dimension growing with the length and products of complete graphs of any dimension (answering a question asked in [31]). We state our most general theorem in Section 1.5 and illustrate its use with some examples.

The problem of establishing a phase transition for the appearance of a component of size order 2^m was solved in the breakthrough work of Ajtai, Komlós and Szemerédi [3]. They proved that when the retention probability of an edge is scaled as $p = c/m$ for a fixed constant $c > 0$ the model exhibits a phase transition: if $c < 1$, then the largest component has size of order m and if $c > 1$, then the largest component has size linear in 2^m , with high probability.

At about the same time, Bollobás [13] initiated a study of zooming in onto the large scale properties of the phase transition on the Erdős and Rényi [23] random graph $G(n, p)$ (see Section 1.1 below). However, unlike $G(n, p)$, the phase transition in the hypercube does *not* occur around $p = 1/(\deg - 1)$, where \deg denotes the degree of the graph. In fact, it was shown by the first author and Slade [34, 35] that p_c of the hypercube $\{0, 1\}^m$ satisfies

$$p_c = \frac{1}{m-1} + \frac{7/2}{m^3} + O(m^{-4}), \quad (1.2)$$

Here and below we write $f(m) = O(g(m))$ if $|f(m)|/|g(m)|$ is uniformly bounded from above by a positive constant, $f(m) = \Theta(g(m))$ if $f(m) = O(g(m))$ and $g(m) = O(f(m))$ and $f(m) = o(g(m))$ if $f(m)/g(m)$ tends to 0 with m . We also say that a sequence of events $(E_m)_{m \geq 1}$ *occurs with high probability* (whp) when $\lim_{m \rightarrow \infty} \mathbf{P}(E_m) = 1$.

The first improvement to [3] was obtained by Bollobás, Kohayakawa and Łuczak [15]. They showed that if $p = (1 + \varepsilon_m)/(m - 1)$ with $\varepsilon_m = o(1)$ but $\varepsilon_m \geq 60m^{-1}(\log m)^3$, then $|\mathcal{C}_1| = (2 + o(1))\varepsilon_m 2^m$ whp. In view of (1.2), it is clear that one cannot improve the regime of ε_m in their result to more than $\varepsilon_m \geq m^{-2}$. In [18], the authors show that when $\varepsilon_m \geq e^{-cm^{1/3}}$ and $p = p_c(1 + \varepsilon_m)$, then $|\mathcal{C}_1| \geq c\varepsilon_m 2^m$ whp. Note that $e^{-cm^{1/3}} \gg 2^{-\alpha m}$ for any $\alpha > 0$ so the requirement on ε_m of Theorem 1.1 is much weaker. Our result, combined with those in [16, 17, 18], shows that it is sharp and therefore fully identifies the phase transition on the hypercube.

Other models of statistical physics, such as random minimal spanning trees and bootstrap percolation on the hypercube have been studied before, we refer the reader to [7, 8, 49]. In the remainder of this section we present some of the necessary background and context of the result, briefly describe our techniques (we provide a more detailed overview of the proof in the next section) and present a general theorem which is used to establish scaling windows for percolation on various other graphs studied in the literature.

1.1. The Erdős and Rényi random graph. Recall that $G(n, p)$ is obtained from the complete graph by retaining each edge of the complete graph on n vertices with probability p and erasing it otherwise, independently for all edges. Write \mathcal{C}_j for the j th largest component obtained this way. An inspiring

discovery of Erdős and Rényi [23] is that this model exhibits a phase transition when p is scaled like $p = c/n$. When $c < 1$ we have $|\mathcal{C}_1| = \Theta(\log n)$ whp and $|\mathcal{C}_1| = \Theta(n)$ whp when $c > 1$.

The investigation of the case $c \sim 1$, initiated by Bollobás [13] and further studied by Łuczak [43], revealed an intricate picture of the phase transition's nature. See [14] for results up to 1984, and [4, 37, 38, 44] for references to subsequent work. We briefly describe these here.

The critical window. When $p = (1 + O(n^{-1/3}))/n$, for any fixed integer $j \geq 1$,

$$\left(\frac{|\mathcal{C}_1|}{n^{2/3}}, \dots, \frac{|\mathcal{C}_j|}{n^{2/3}} \right) \xrightarrow{d} (\chi_1, \dots, \chi_j),$$

where $(\chi_i)_{i=1}^j$ are random variables supported on $(0, \infty)$, and \xrightarrow{d} denotes convergence in distribution.

The subcritical phase. Let $\varepsilon_n = o(1)$ be a non-negative sequence with $\varepsilon_n \gg n^{-1/3}$ and put $p = (1 - \varepsilon_n)/n$, then, for any fixed integer $j \geq 1$,

$$\frac{|\mathcal{C}_j|}{2\varepsilon_n^{-2} \log(\varepsilon_n^3 n)} \xrightarrow{\mathbb{P}} 1.$$

The supercritical phase. Let $\varepsilon_n = o(1)$ be a non-negative sequence with $\varepsilon_n \gg n^{-1/3}$ and put $p = (1 + \varepsilon_n)/n$, then

$$\frac{|\mathcal{C}_1|}{2\varepsilon_n n} \xrightarrow{\mathbb{P}} 1,$$

and, for any fixed integer $j \geq 2$,

$$\frac{|\mathcal{C}_j|}{2\varepsilon_n^{-2} \log(\varepsilon_n^3 n)} \xrightarrow{\mathbb{P}} 1.$$

Thus, the prominent qualitative features of this phase transition are:

- (1) The emergence of the giant component occurs just above the scaling window. That is, only in the supercritical phase we have that $|\mathcal{C}_2| \ll |\mathcal{C}_1|$, and that $|\mathcal{C}_1|/n$ increases suddenly but smoothly above the critical value (in mathematical physics jargon, the phase transition is of second order).
- (2) Concentration of the size of the largest connected components outside the scaling window and non-concentration inside the window.
- (3) Duality: $|\mathcal{C}_2|$ in the supercritical phase has the same asymptotics as $|\mathcal{C}_1|$ in the corresponding subcritical phase.

Theorem 1.1 shows that (1) and (2) occurs on the hypercube (the non-concentration of $|\mathcal{C}_1|$ at p_c was proved in [30]). Property (3) on the hypercube remains an open problem (see Section 8).

1.2. Random subgraphs of transitive graphs. Let us briefly review the study of percolation on finite transitive graphs presented in [16, 17, 18] (see also [6]). We focus here only on some of the many results obtained in these papers. Let G be a finite transitive graph and write V for the number of vertices of G . Let $p \in [0, 1]$ and write G_p for the random graph obtained from G by retaining each edge with probability p and erasing it with probability $1 - p$, independently for all edges. We also write \mathbf{P}_p for this probability measure. We say an edge is p -open (p -closed) if was retained (erased). We say that a path in the graph is p -open if all of its edges are p -open. For two vertices x, y we write $x \leftrightarrow y$ for the event that there exists a p -open path connecting x and y . For an integer $j \geq 1$ we write \mathcal{C}_j for the j th largest component of G_p (breaking ties arbitrarily) and for a vertex v we write $\mathcal{C}(v)$ for the component in G_p containing v .

For two vertices x, y we denote

$$\nabla_p(x, y) = \sum_{u, v} \mathbf{P}_p(x \leftrightarrow u) \mathbf{P}_p(u \leftrightarrow v) \mathbf{P}_p(v \leftrightarrow y). \quad (1.3)$$

The quantity $\nabla_p(x, y)$, known as the *triangle diagram*, was introduced by Aizenman and Newman [2] to study critical percolation on high-dimensional infinite lattices. In that setting, the important feature of an infinite graph G is whether $\nabla_{p_c}(0, 0) < \infty$. This condition is often referred to as the *triangle condition*. In high-dimensions, Hara and Slade [28] proved the triangle condition. It allows to deduce that numerous critical exponents attain the same values as they do on an infinite regular tree, see e.g. [9, 2, 39, 41].

When G is a finite graph, $\nabla_p(0, 0)$ is obviously finite, however, there is still a *finite* triangle condition which in turn guarantees that random critical subgraphs of G have the same geometry as random subgraphs of the complete graph on V vertices, where V denotes the number of vertices in G . That is, in the finite setting the role of the infinite regular tree is played by the complete graph. Let us make this heuristic formal.

We always have that $V \rightarrow \infty$ and that $\lambda \in (0, 1)$ is a fixed constant. Let $p_c = p_c(\lambda)$ be defined by

$$\mathbb{E}_{p_c(\lambda)} |\mathcal{C}(0)| = \lambda V^{1/3}. \quad (1.4)$$

The finite triangle condition is the assumption that $\nabla_{p_c(\lambda)}(x, y) \leq \mathbf{1}_{\{x=y\}} + a_0$, for some $a_0 = a_0(\lambda)$ sufficiently small. The strong triangle condition, defined in [17, (1.26)], is the statement that there exists a constant C such that for all $p \leq p_c$,

$$\nabla_p(x, y) \leq \mathbf{1}_{\{x=y\}} + C\chi(p)^3/V + \alpha_V, \quad (1.5)$$

where $\alpha_V \rightarrow 0$ as $m \rightarrow \infty$ and $\chi(p) = \mathbb{E}_p |\mathcal{C}(0)|$ denotes the expected cluster size. Throughout this paper, we will assume that the strong triangle condition holds. In fact, in all examples where the finite triangle condition is proved to hold, actually the strong triangle condition (1.5) is proved. In [17], (1.5) is shown to hold for various graphs: the complete graph, the hypercube and high-dimensional tori \mathbb{Z}_n^d . In particular, the next theorem states (1.5) for the hypercube.

Theorem 1.2 ([17]). *Consider percolation on the hypercube $\{0, 1\}^m$. Then for any λ , there exists a constant $C = C(\lambda) > 0$ such that for any $p \leq p_c(\lambda)$ (as defined in (1.4))*

$$\nabla_p(x, y) \leq \mathbf{1}_{\{x=y\}} + C(\chi(p)^3/V + 1/m). \quad (1.6)$$

As we discuss in Remark 4 below Theorem 1.3, our methodology can be used to yield a simple proof of Theorem 1.2 without relying on the lace-expansion methods derived in [17]. The main effort in [16] is to show that under condition (1.5) the phase transition behaves similarly to the one in $G(n, p)$ described in the previous section. The main results obtained in [16] are the following:

The critical window. Let G be a finite transitive graph for which (1.5) holds. Then, for $p = p_c(1 + O(V^{-1/3}))$,

$$\mathbf{P}(A^{-1}V^{2/3} \leq |\mathcal{C}_1| \leq AV^{2/3}) = 1 - O(A^{-1}).$$

The subcritical phase. Let G be a finite transitive graph for which (1.5) holds. Let $\varepsilon = o(1)$ be a non-negative sequence with $\varepsilon \gg V^{-1/3}$ and put $p = p_c(1 - \varepsilon)$. Then, for all fixed $\delta > 0$,

$$\mathbf{P}(|\mathcal{C}_1| \leq (2 + \delta)\varepsilon^{-1} \log(\varepsilon^3 V)) = 1 - o(1).$$

The supercritical phase. Let G be a finite transitive graph for which (1.5) holds. Let $\varepsilon = o(1)$ be a non-negative sequence with $\varepsilon \gg V^{-1/3}$ and put $p = p_c(1 + \varepsilon)$. Then,

$$\mathbf{P}(|\mathcal{C}_1| \geq A\varepsilon V) = O(A^{-1}).$$

Thus, while these results hold in a very general setting, they are incomplete. Most notably, in the supercritical phase there is no matching lower bound on $|\mathcal{C}_1|$. So, a priori, it is possible that $|\mathcal{C}_1|$ is

still of order $V^{2/3}$ when $p = p_c(1 + \varepsilon)$ for some $\varepsilon \gg V^{-1/3}$ and that the scaling window is in fact much larger than $V^{-1/3}$. It remains an open problem to show whether (1.5) by itself implies that $|\mathcal{C}_1|/(\varepsilon V)$ converges in probability to a constant in the supercritical phase.

As we mentioned before, the particular case of the hypercube was addressed in [18]. There the authors employed some of the result of [16, 17] together with a *sprinkling* argument to provide a lower bound of order $\varepsilon 2^m$ on $|\mathcal{C}_1|$ valid only when $\varepsilon \geq e^{-cm^{1/3}}$. We will rely on the sprinkling method for the arguments in this paper, so let us briefly expand on it.

1.3. Sprinkling. The sprinkling technique was invented by Ajtai, Komlós and Szemerédi [3] to show that $|\mathcal{C}_1| = \Theta(2^m)$ when $p = (1 + \varepsilon)/m$ for fixed $\varepsilon > 0$ and can be described as follows. Fix some small $\theta > 0$ and write $p_1 = (1 + (1 - \theta)\varepsilon)/m$ and $p_2 \geq \theta\varepsilon/m$ such that $(1 - p_1)(1 - p_2) = 1 - p$. It is clear that G_p is distributed as the union of the edges in two independent copies of G_{p_1} and G_{p_2} . The sprinkling method consists of two steps. The first step is performed in G_{p_1} and uses a branching process comparison argument together with Azuma-Hoeffding concentration inequality to obtain that whp at least $c_2 2^m$ vertices are contained in connected components of size at least $2^{c_1 m}$ for some small but fixed constants $c_1, c_2 > 0$. In the second step we add the edges of G_{p_2} (these are the “sprinkled” edges) and show that they connect many of the clusters of size at least $2^{c_1 m}$ into a giant cluster of size $\Theta(2^m)$.

Let us give some details on how the last step is done. A key tool here is the *isoperimetric inequality* for the hypercube stating that two disjoint subsets of the hypercube of size at least $c_2 2^m/3$ have at least $2^m/m^{100}$ disjoint paths of length $C(c_2)\sqrt{m}$ connecting them, for some constant $C(c_2)$. (The m^{100} in the denominator is not sharp, but this is immaterial as long as it is a polynomial in m .) This fact is used in the following way. Write V' for the set of vertices which are contained in a component of size at least $2^{c_1 m}$ in G_{p_1} so that $V' \geq c_2 2^m$. We say that *sprinkling fails* when $|\mathcal{C}_1| \leq c_2 2^m/3$ in the union $G_{p_1} \cup G_{p_2}$. If sprinkling fails, then we can partition $V' = A \uplus B$ such that both A and B have cardinality at least $c_2 2^m/3$ and *any* path of length at most $C(c_2)\sqrt{m}$ between them has an edge which is p_2 -closed. The number of such partitions is at most $2^{2^m/2^{c_1 m}}$. The probability that a path of length k has a p_2 -closed edge is $1 - p_2^k$. Applying the isoperimetric inequality and using that the paths guaranteed to exist by it are disjoint so that the edges in them are independent, the probability that sprinkling fails is at most

$$2^{2^m/2^{c_1 m}} \cdot \left(1 - \left(\frac{\theta\varepsilon}{m}\right)^{C(c_2)\sqrt{m}}\right)^{2^m/m^{100}} = e^{-2^{(1+o(1))m}}, \quad (1.7)$$

which tends to 0.

1.4. Revised sprinkling. The sprinkling argument above is not optimal due to the use of the isoperimetric inequality. It is wasteful because it assumes that large percolation clusters can be “worst-case” sets, that is, sets which saturate the isoperimetric inequality (e.g., two balls of radius $m/2 - \sqrt{m}$ around two vertices at Hamming distance m). However, it is in fact very improbable for percolation clusters to be similar to this kind of worst-case sets. Our approach replaces the use the isoperimetric inequality by proving statements showing that large percolation clusters are “close” to uniform random sets of similar size. It allows us to deduce that two large clusters share many closed edges with the property that if we open even *one* of them, then the two clusters connect. While previously we had paths of length \sqrt{m} connecting the two clusters, here we will have paths of length precisely 1. The final line of our proof, replacing (1.7), will be

$$2^{2\varepsilon V/(k_m \varepsilon^{-2})} \cdot \left(1 - \frac{\theta\varepsilon}{m}\right)^{m\varepsilon^2 V} \leq e^{-\theta\varepsilon^3 V(1+o(1))}, \quad (1.8)$$

where k_m is some sequence with $k_m \rightarrow \infty$ very slowly. This tends to 0 since $\varepsilon^3 V \rightarrow \infty$. Compared with the logic leading to (1.7), this line is rather suggestive. We will obtain that whp $2\varepsilon V$ vertices are in components of size at least $k_m \varepsilon^{-2}$, explaining the $2^{2\varepsilon V/(k_m \varepsilon^{-2})}$ factor in (1.8). The main effort in this

paper is to justify the second factor showing that for any partition of these vertices into two sets of size εV , the number of closed edges between them is at least $\varepsilon^2 m V$ — the same number of edges one would expect two uniform random sets of size εV to have between them. Therefore, given a partition, the probability that sprinkling fails for it is bounded by $\left(1 - \frac{\theta\varepsilon}{m}\right)^{m\varepsilon^2 V}$.

1.5. The general theorem. Our methods use relatively simple geometric properties of the hypercube and apply to a larger set of underlying graphs. We present this general setting that the majority of the paper assumes and briefly discuss some other cases for which our main theorem holds aside from the hypercube. We remark that the impatient reader may proceed assuming the underlying graph is always the hypercube $\{0, 1\}^m$ — we have set up the notation to support this since the hypercube, in some sense, is our most “difficult” example.

The geometric conditions of our underlying graphs will be stated in terms of random walks. The main advantage of this approach is that these conditions are relatively easy to verify. Let G be a finite transitive graph on V vertices and degree m . Consider the non-backtracking random walk on it (this is just a simple random walk not allowed to traverse back on the edge it just came from, see Section 3.4 for a precise definition). For any two vertices x, y , we put $\mathbf{p}^t(x, y)$ for the probability that the walk started at x visits y at time t . For any $\xi > 0$, we write $T_{\text{mix}}(\xi)$ for the ξ -uniform mixing time of the walk, that is,

$$T_{\text{mix}}(\xi) = \min \left\{ t : \max_{x, y} \frac{\mathbf{p}^t(x, y) + \mathbf{p}^{t+1}(x, y)}{2} \leq (1 + \xi) V^{-1} \right\}.$$

Theorem 1.3. *Let G be a transitive graph on V vertices with degree m and define p_c as in (1.1) with $\lambda = 1/10$. Assume that there exists a sequence $\alpha_V = o(1)$ with $\alpha_V \geq 1/m$ such that if we put $m_0 = T_{\text{mix}}(\alpha_V)$, then the following conditions hold:*

- (1) $m \rightarrow \infty$ as $V \rightarrow \infty$,
- (2) $[p_c(m-1)]^{m_0} = 1 + O(\alpha_V)$,
- (3) For any vertices x, y ,

$$\sum_{u, v} \sum_{\substack{t_1, t_2, t_3=0 \\ t_1+t_2+t_3 \geq 3}}^{m_0} \mathbf{p}^{t_1}(x, u) \mathbf{p}^{t_2}(u, v) \mathbf{p}^{t_3}(v, y) = O(\alpha_V / \log V).$$

Then,

- (a) the finite triangle condition (1.5) holds (and hence the results in [16] described in Section 1.2 hold),
- (b) for any sequence $\varepsilon = \varepsilon_m$ satisfying $\varepsilon_m \gg V^{-1/3}$ and $\varepsilon_m = o(m_0^{-1})$,

$$\frac{|\mathcal{C}_1|}{2\varepsilon_m V} \xrightarrow{\mathbb{P}} 1, \quad \mathbb{E}|\mathcal{C}(0)| = (4 + o(1))\varepsilon_m^2 V, \quad \frac{|\mathcal{C}_2|}{\varepsilon_m V} \xrightarrow{\mathbb{P}} 0.$$

Remark 1. In the case of the hypercube $\{0, 1\}^m$ we will take $\alpha_V = m^{-1} \log m$ and verify the conditions of Theorem 1.3. This is done in Section 7. Although the behavior of random walk on the hypercube is well understood, we were not able to find an estimate on the uniform mixing time yielding $T_{\text{mix}}(m^{-1} \log m) = \Theta(m \log m)$ in the literature. To show this we use the recent paper of Fitzner and the first author [25] in which the non-backtracking walk transition matrix on the hypercube is analyzed. We use this result in Lemma 7.1 to verify condition (3) and condition (2) follows directly from (1.2) (though condition (2) can be verified by elementary means without using (1.2), see Remark 4).

Remark 2. Note that part (b) of Theorem 1.3 only applies when $\varepsilon_m = o(m_0^{-1})$ and not for any $\varepsilon_m = o(1)$. Thus, for a complete proof of Theorem 1.1, we also require a separate argument dealing with the regime $\varepsilon_m \geq cm_0^{-1}$ — in the case of the hypercube and other graphs mentioned in this paper, this is a

much easier regime in which previous techniques based on sprinkling and isoperimetric inequalities are effective.

Remark 3. Random walk conditions for percolation on finite graphs were first given by the second author in [46]. The significant difference between the two approaches is that in [46] the condition requires controlling the random walk behavior for a period of time which is as long as the critical cluster diameter, that is, $V^{1/3}$. The outcome is that the results of [46] only apply when $p_c = (1 + O(V^{-1/3})) / (m - 1)$ and hence do not apply in the case of the hypercube. Here we are only interested in the behavior of the random walk up to the mixing time, even though that typical percolation paths are much longer. The reason for this is that it turns out that it is enough to randomize the beginning of a percolation path in order to obtain that the end point is uniformly distributed, see Section 2.4. Another difference is that the results in [46] only show that $|\mathcal{C}_1| \geq c\varepsilon V$ for some $c > 0$ and do not give the precise asymptotic value of $|\mathcal{C}_1|$ as we do here.

Remark 4. Our approach also enables us to give a simple proof for the fact that the finite triangle condition (Theorem 1.2) holds for the hypercube without using the lace expansion as in [17], and is performed in [33]. Our proof of this fact relies on the estimate $p_c = 1/(m - 1) + O(m^{-3})$ (which is much weaker than (1.2) but also much easier to prove) and on the argument presented in Section 2.4. In fact, in the current paper we only rely on this easy estimate for p_c so our main result here, Theorem 1.1, is in fact self-contained and does not rely at any time on results obtained via the lace expansion in [17] (we do use arguments of [16] which rely on the triangle condition). We refer to [33] for a more extensive discussion on this subject.

In many cases, verifying the conditions of Theorem 1.3 is done using known methods from the theory of percolation and random walks (note that condition (2) involves both a random walk and a percolation estimate). We illustrate how to perform this in Section 7 in the case of the hypercube (thus proving Theorem 1.1) and for expander families of high degree and high girth (see [36] for an introduction to expanders). This is a class of graphs that contains various examples such as Payley graphs (see e.g. [21]), products K_n^d of complete graphs and many others. Percolation on products of complete graphs were studied in [31, 32, 46] in the cases $d = 2, 3$; our expander theorem allows us to provide a complete description of the phase transition in any fixed dimension d , answering a question posed in [31]. Recall that a sequence of graphs G_n is called an *expander* family if there exists a constant $c > 0$ such that the second largest eigenvalue of the transition matrix of the simple random walk is at most $1 - c$ (the largest eigenvalue is 1). Also, the girth of a graph is the length of the shortest cycle. It is a classical fact that on expanders $T_{\text{mix}}(V^{-1}) = O(\log V)$, where V is the number of vertices of the graph, see e.g. [5, below (19)].

Theorem 1.4. *Let G_m be a transitive family of expanders with degree $m \rightarrow \infty$ and V vertices. Assume that $m \geq c \log V$ and that the girth of G is at least $c \log_{m-1} V$ for some fixed $c > 0$. Then the conditions of Theorem 1.3 hold and hence the conclusions of that theorem hold.*

For products K_n^d of complete graphs, the girth equals 3, $V = n^d$ and $m = d(n - 1)$, so that the girth assumption is satisfied for $c \leq 3(1 - o(1))/d$ and n sufficiently large. Theorem 1.3 applies to other examples of graphs, not included in the last theorem, for example, products of complete graphs K_n^d where d may depend on n (as long as $n + d \rightarrow \infty$) and finite tori \mathbb{Z}_n^d but only when $d = d(n)$ grows at some rate with n . We omit the details since they are rather similar. We emphasize, however, that there are important examples which our methods are insufficient to solve. Most prominently are bounded degree expanders with low girth (the case of girth $\geq (2/3 + \varepsilon) \log_{m-1}(n)$ was solved in [46]) and finite tori \mathbb{Z}_n^d where d is large but fixed. It seems that new ideas are required to study percolation on these graphs, see Section 8.

1.6. Organization. This paper is organized as follows. In Section 2 we give an overview of our proof, stating the main results upon which the proof is based. In Section 3 we prove several estimates on the number of vertices satisfying various properties, such as having large clusters, or surviving up to great depth. We further prove detailed estimates on connection probabilities. In Section 4 we prove expected volume estimates both in the critical and supercritical regimes. In Section 5 we prove an intrinsic-metric regularity theorem, showing that most vertices that survive long and have a large cluster size have neighborhoods that are sufficiently regular. See Section 2 for an explanation on how the estimates of Sections 4 and 5 are used in the proof. In Section 6 we show that most large clusters have many closed edges between them, which is the main result in our proof. In Section 7 we perform the improved sprinkling argument as indicated in Section 1.4, and complete the proof of Theorem 1.1. In Section 8 we discuss several open problems. We close the paper with Appendix A where we sharpen the arguments in [9] and [17] to obtain the asymptotics of the supercritical cluster tail.

1.7. Acknowledgements. The work of RvdH was supported in part by the Netherlands Organization for Scientific Research (NWO). The work of AN was partially supported by NSF grant #6923910. RvdH warmly thanks the Theory Group at Microsoft Research Redmond for the hospitality during his visit in January 2010, where this work was initiated, the Department of Mathematics at M.I.T. for their hospitality during his visit in April 2011, and the Department of Mathematics at U.B.C. for their hospitality during his visit in November 2011. We thank Gady Kozma for useful discussions and Gordon Slade for valuable comments on a preliminary version of this paper. AN thanks Christian Borgs for introducing him to [18, Conjecture 3.2] when he was an intern at Microsoft Research in the summer of 2005.

2. OVERVIEW OF THE PROOF

In this section we give an overview of the key steps in our proof. Throughout the rest of the paper we assume that $\varepsilon = \varepsilon_m$ is a sequence such that $\varepsilon = o(1)$ but $\varepsilon^3 V \rightarrow \infty$.

2.1. Notations and tools. Let G be a transitive graph and recall that G_p is obtained from G by independently retaining each edge with probability p . Recall that $x \leftrightarrow y$ denotes that there exists a p -open path connecting x and y . We write $d_{G_p}(x, y)$ for the length of a shortest p -open path between x, y and put $d_{G_p}(x, y) = \infty$ if x is not connected to y in G_p . We write $x \xrightarrow{r} y$ if $d_{G_p}(x, y) \leq r$, we write $x \xrightarrow{=r} y$ if $d_{G_p}(x, y) = r$ and $x \xleftrightarrow{[a,b]} y$ if $d_{G_p}(x, y) \in [a, b]$. Further, we write $x \xleftrightarrow{P[a,b]} y$ when there exists an open path of length in $[a, b]$ between x and y (not necessarily a shortest path). The event $\{x \xleftrightarrow{[a,b]} y\}$ is not increasing with respect to adding edges, but the event $\{x \xleftrightarrow{P[a,b]} y\}$ is, which often makes it easier to deal with. Whenever the sign \leftrightarrow appears it will be clear what p is and we will drop it from the notation. The *intrinsic metric* ball of radius r around x and its boundary are defined by

$$B_x^G(r) = \{y: d_{G_p}(x, y) \leq r\}, \quad \partial B_x^G(r) = \{y: d_{G_p}(x, y) = r\}.$$

Note that these are random sets of the graph and not the balls in shortest path metric of the graph G . We often drop the G from the above notation and write $B_x(r)$ when it is clear what the underlying graph G is. We also denote

$$B_x^G([a, b]) = \{y: x \xleftrightarrow{[a,b]} y\}.$$

Our graphs always contain a marked vertex that we call *the origin* and denote by 0 . In the case of the hypercube this is taken to be the all 0 vector. We often drop 0 from notation and write $B(r)$ for $B_0(r)$ whenever possible.

We now define the intrinsic metric *one-arm* event. This was introduced in [48] to study the mixing time of critical $G(n, p)$ clusters and was very useful in the context of high-dimensional percolation in [39]. Define the event

$$H^G(r) = \{\partial B_0^G(r) \neq \emptyset\},$$

for any integer $r \geq 0$ and

$$\Gamma(r) = \sup_{G' \subset G} \mathbf{P}(H^{G'}(r)), \quad (2.1)$$

where the supremum is over all subgraphs G' of G . The reason for the somewhat unnatural definition of Γ above is the fact that the event $\partial B_0^G(r) \neq \emptyset$ is not monotone with respect to the addition of edges. Indeed, turning an edge from closed to open may shorten a shortest path rendering the configuration such that the event $\partial B_0^G(r) \neq \emptyset$ no longer occurs. This non-monotonicity problem is arising whenever one conditions on $B_0^G(r)$ and would like to estimate the probability that some $v \in \partial B_0^G(r)$ survives an additional ℓ generations, that is, that $\partial B_v^G(\ell) \neq \emptyset$ off of $B_0^G(r)$. A priori, the survival probability may be much larger on the subgraph $G \setminus B_0^G(r)$; the next theorem shows this is not the case.

The following theorem studies the survival probability and expected ball sizes at p_c , and is the finite graph analogue of a theorem of Kozma and the second author [39]. The proof is almost identical to the one in [39] and is stated explicitly in [30, 40].

Theorem 2.1 (Volume and survival probability [39]). *Let G be a finite transitive graph on V vertices such that the finite triangle condition (1.5) holds, and consider percolation on G at $p = p_c(\lambda)$ with any $\lambda > 0$. Then there exists a constant $C = C(\lambda) > 0$ such that for any $r > 0$,*

- (1) $\mathbb{E}|B(r)| \leq Cr$, and
- (2) $\Gamma(r) \leq C/r$.

We often need to consider percolation performed at different values of p . We write \mathbf{P}_p and \mathbb{E}_p for the probability distribution and the corresponding expectation operator with parameter p when necessary. Furthermore, we sometimes need to consider percolation configurations at different p 's on the same probability space. This is a standard procedure called the *simultaneous coupling* and it works as follows. For each edge e of our graph G , we draw an independent uniform random variable $U(e)$ in $[0, 1]$. We say that the edge e receives the value $U(e)$. For any $p \in [0, 1]$, the set of p -open edges is distributed precisely as $\{e: U(e) \leq p\}$. In this way, $G_{p_1} \subset G_{p_2}$ with probability 1 whenever $p_1 \leq p_2$.

2.2. Tails of the supercritical cluster size. We start by describing the tail of the cluster size in the supercritical regime. Note that the following theorem requires only the finite triangle condition, and not the stronger assumptions of Theorem 1.3 and so the restriction $\varepsilon = o(m_0^{-1})$ is not needed.

Theorem 2.2 (Bounds on the cluster tail). *Let G be a finite transitive graph of degree m on V vertices such that the finite triangle condition (1.5) holds and put $p = p_c(1 + \varepsilon)$ where $\varepsilon = o(1)$ and $\varepsilon \gg V^{-1/3}$. Then, for any k satisfying $k \gg \varepsilon^{-2}$*

$$\mathbf{P}(|\mathcal{C}(0)| \geq k) \leq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3 V)^{-1} + (\varepsilon^2 k)^{-1/4} + \alpha_V)), \quad (2.2)$$

and, for the sequence $k_0 = \varepsilon^{-2}(\varepsilon^3 V)^\alpha$ for any $\alpha \in (0, 1/3)$, there exists a $c = c(\alpha) > 0$ such that

$$\mathbf{P}(|\mathcal{C}(0)| \geq k_0) \geq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3 V)^{-c} + \alpha_V)). \quad (2.3)$$

Theorem 2.2 is reminiscent of the fact that a branching process with Poisson progeny distribution of mean $1 + \varepsilon$ has survival probability of $2\varepsilon(1 + O(\varepsilon))$ when $\varepsilon = o(1)$. Upper and lower bounds of order ε for the cluster tail were proved already in [17] using Barsky and Aizenman's differential inequalities [9]. However, to get the precise constant 2 we need to sharpen these differential inequalities and handle some error terms in them that were neglected in the past. This derivation and the proof of Theorem 2.2 are presented in Appendix A. Its proof is entirely self-contained.

Let $Z_{\geq k}$ denote the number of vertices with cluster size at least k , i.e.,

$$Z_{\geq k} = |\{v: |\mathcal{C}(v)| \geq k\}|. \quad (2.4)$$

We use Theorem 2.2 to show that $Z_{\geq k_0}$, with k_0 as in the theorem, is concentrated. This advances us towards the first factor on the left hand side of (1.8).

Lemma 2.3 (Concentration of $Z_{\geq k_0}$). *In the setting of Theorem 2.2, if $m \rightarrow \infty$, then*

$$\frac{Z_{\geq k_0}}{2\varepsilon V} \xrightarrow{\mathbb{P}} 1,$$

and

$$\mathbb{E}|\mathcal{C}(0)| \leq (4 + o(1))\varepsilon^2 V.$$

2.3. Many boundary edges between large clusters. The factor $(1 - \frac{\theta\varepsilon}{m})^{m\varepsilon^2 V}$ in (1.8) suggests that after partitioning the large clusters into two sets of order εV vertices, as we did before, the number of closed edges connecting them is of order $m\varepsilon^2 V$. This is the content of Theorem 2.4 below which is the main effort of this paper. It is rather intuitive if one believes that large clusters are uniform random sets. Indeed, let v be a vertex in one of the sets of the partition. It has degree m and hence we expect $m\varepsilon$ of these neighbors to belong to the second set of the partition. Summing over all vertices v we obtain of the order $\varepsilon^2 mV$ edges. Making this a precise statement requires some details which we now provide.

We work under the general assumptions of Theorem 1.3. In particular, we are given sequences ε_m, α_V such that both are $o(1)$ and $\varepsilon_m^3 V \rightarrow \infty$ and $\alpha_V \geq 1/m$. Without loss of generality we assume that

$$\alpha_V \geq (\varepsilon_m^3 V)^{-1/2}, \quad (2.5)$$

otherwise we replace the original α_V by $(\varepsilon_m^3 V)^{-1/2}$, and note that in both cases $\alpha_V = o(1)$ and satisfies $\alpha_V \geq 1/m$.

Let us start by introducing some notation. For vertices x, y and radii j_x, j_y , we define the event

$$\mathcal{A}(x, y, j_x, j_y) = \{\partial B_x(j_x) \neq \emptyset, \partial B_y(j_y) \neq \emptyset \text{ and } B_x(j_x) \cap B_y(j_y) = \emptyset\} \quad (2.6)$$

Intuitively, if $\mathcal{A}(x, y, j_x, j_y)$ occurs for j_x and j_y sufficiently large, then x and y are both in the giant component. The event $\mathcal{A}(x, y, j_x, j_y)$ plays a central role throughout our paper. We continue by choosing some parameters. The role of each will become clear later. We put

$$M = M_m = \log \log \log(\varepsilon^3 V \wedge \alpha_V^{-1} \wedge (\varepsilon m_0)^{-1}) \quad \text{and} \quad r = r_m = M_m \varepsilon^{-1}. \quad (2.7)$$

Note that $M_m \rightarrow \infty$ in our setting. We choose r_0 by

$$r_0 = \frac{\varepsilon^{-1}}{2} \log(\alpha_V \varepsilon^3 V). \quad (2.8)$$

In Corollary 4.6 we prove that $\mathbb{E}|B(j)| = \Theta(\varepsilon^{-1}(1 + \varepsilon)^j)$ as long as $j \leq \varepsilon^{-1}[\log(\varepsilon^3 V) - 4 \log \log(\varepsilon^3 V)]$ — the same asymptotics as in a Poisson $(1 + \varepsilon)$ branching process (though in the branching process the estimate is valid for all j). This implies that $\mathbb{E}|B(r_0)| = \Theta(\sqrt{\alpha_V \varepsilon V})$, a fact that we use throughout the paper, but we do not use this right now.

For vertices x, y we define

$$S_{2r+r_0}(x, y) = \left\{ \{(u, u') \in E(G) : \{x \xleftrightarrow{2r+r_0} u\} \circ \{y \xleftrightarrow{2r+r_0} u'\}\}, \right. \\ \left. |B_u(2r+r_0)| \cdot |B_{u'}(2r+r_0)| \leq e^{40M} \varepsilon^{-2} (\mathbb{E}|B(r_0)|)^2 \right\}.$$

The edges counted in $S_{2r+r_0}(x, y)$ are the ones that will be used in the sprinkling. Informally, a pair of vertices (x, y) is *good* when their clusters are large and $S_{2r+r_0}(x, y)$ is large, so that their clusters have many bonds between them. We make this quantitative in the following definition:

Definition 2.1 ((r, r_0) -good pairs). *We say that x, y are (r, r_0) -good if all of the following occur:*

- (1) $\mathcal{A}(x, y, 2r, 2r)$,
- (2) $|\mathcal{C}(x)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}$ and $|\mathcal{C}(y)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}$,
- (3) $S_{2r+r_0}(x, y) \geq (\log M)^{-1} V^{-1} m \varepsilon^{-2} (\mathbb{E}|B(r_0)|)^2$.

Write P_{r,r_0} for the number of (r, r_0) -good pairs.

Theorem 2.4 (Most large clusters share many boundary edges). *Let G be a graph on V vertices and degree m satisfying the assumptions in Theorem 1.3. Assume that $\varepsilon = \varepsilon_m$ satisfies*

$$\varepsilon_m \gg V^{-1/3} \quad \text{and} \quad \varepsilon_m = o(m_0^{-1}), \quad (2.9)$$

as in part (b) of Theorem 1.3. Take M and $r = M\varepsilon^{-1}$ as in (2.7), and r_0 as in (2.8). Then,

$$\frac{P_{r,r_0}}{(2\varepsilon V)^2} \xrightarrow{\mathbb{P}} 1.$$

In light of Theorem 2.2, we expect that the number of pairs of vertices (x, y) with $|\mathcal{C}(x)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}$ and $|\mathcal{C}(y)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}$ is close to $(2\varepsilon V)^2$. Theorem 2.4 shows that the majority of these pairs have clusters that share many edges between them. This allows us to proceed with the sprinkling argument leading to (1.8) and we perform this in Section 7.1 leading to the proof of Theorem 1.3. Since the latter proof assumes only Theorem 2.4, the curious reader may skip now to Section 7.1 to see how this is done.

2.4. Uniform connection bounds and the role of the random walk. We briefly expand here on one of our most useful percolation inequalities and its connection with random walks. In the analysis of the Erdős-Rényi random graph $G(n, p)$ symmetry plays a special role. One instance of this symmetry is that the function $f(x) = \mathbf{P}(0 \leftrightarrow x)$ is constant whenever $x \neq 0$ and its value is precisely $(V-1)^{-1}(\mathbb{E}|\mathcal{C}(0)| - 1)$, and 1 when $x = 0$. Such a statement clearly does not hold on the hypercube at p_c : the probability that two neighbors are connected is at least m^{-1} (recall (1.2)) and the probability that 0 is connected to one of the vertices in the barycenter of the cube is at most $\sqrt{m}2^{-m}\mathbb{E}|\mathcal{C}(0)|$ by symmetry.

A key observation in our proof is that one can recover this symmetry as long as we require the connecting paths to be longer than the mixing time of the random walk. A precise statement is that percolation at p_c on any graph G satisfying the assumptions of Theorem 1.3,

$$\mathbf{P}(0 \xleftrightarrow{[m_0, \infty)} x) \leq (1 + o(1)) \frac{\mathbb{E}|\mathcal{C}(0)|}{V}, \quad (2.10)$$

where m_0 is uniform mixing time, as defined in Theorem 1.3. This is the content of Lemma 3.13 (or rather by taking $r \rightarrow \infty$ in the lemma). In addition to allowing us to estimate difficult sums such as $\nabla_p(0, 0)$ in (1.3) (see Section 3.6) and other similar quantities, this estimate also plays a key role in the high level idea of the proof, as we now explain.

2.5. Sketch of proof of Theorem 2.4. The difficulty in Theorem 2.4 is the requirement (3) in Definition 2.1. Indeed, conditioned on survival (that is, on the event $\mathcal{A}(x, y, 2r, 2r)$), the random variable $S_{2r+r_0}(x, y)$ is not concentrated and hence it is hard to prove that it is large with high probability. In fact, even the variable $|B(r_0)|$ is not concentrated. This is not a surprising fact: the number of descendants at generation n of a branching process with mean $\mu > 1$ divided by μ^n converges as $n \rightarrow \infty$ to a non-trivial random variable. Intuitively, this non-concentration occurs because the first generations of the process have a strong and lasting effect on the future of the population.

In order to counteract this, we condition on the event $\mathcal{A}(x, y, r, r)$ and on the entire balls $B_x(r)$ and $B_y(r)$ including all the open and closed edges touching them (during the actual proof we will use some other radii j_x, j_y between r and $2r$ but this is a technical matter). We will prove that given this conditioning the variable $S_{r+r_0}(x, y)$ is concentrated around the value

$$|\partial B_x(r)| |\partial B_y(r)| V^{-1} m (\mathbb{E}|B(r_0)|)^2, \quad (2.11)$$

and that $|\partial B_x(r)| |\partial B_y(r)| \geq \varepsilon^{-2}$ with high probability, yielding that requirement (3) in Definition 2.1 occurs with high probability conditioned on the event above. Our choice of r_0 in (2.8) is made in such

a way that the above quantity is large (however, later we will see that r_0 cannot be too large). Let us elaborate on the estimate (2.11). Assume that $B_x(r) = A$ and $B_y(r) = B$ and write $\mathbf{P}_{A,B}$ and $\mathbb{E}_{A,B}$ for the conditional probability and expectation given $B_x(r) = A$ and $B_y(r) = B$. We have

$$\mathbb{E}_{A,B} S_{r+r_0}(x, y) \approx \sum_{a \in \partial A, b \in \partial B} \sum_{(u, u')} \mathbf{P}_{A,B}(\{a \xrightarrow{r_0} u\} \circ \{b \xrightarrow{r_0} u'\}),$$

where we did not write equality because a) we ignored the second condition in the definition of $S_{r+r_0}(x, y)$ on $|B_u(2r+r_0)| \cdot |B_{u'}(2r+r_0)|$, and b) some edges (u, u') may be over-counted in the sum, and c) we have neglected to count the closed edges (u, u') that connect A and B (that is, occurring in height smaller than r). However, it turns out that all of these contributions are small compared to (2.11). It is a standard matter by now to use the triangle condition in order to obtain that for *most* edges (u, u')

$$\mathbf{P}_{A,B}(\{a \xrightarrow{r_0} u\} \circ \{b \xrightarrow{r_0} u'\}) \approx \mathbf{P}_{A,B}(a \xrightarrow{r_0} u) \mathbf{P}_{A,B}(b \xrightarrow{r_0} u'),$$

so in order to proceed we need a good lower bound on $\mathbf{P}_{A,B}(a \xrightarrow{r_0} u)$. The uniform connection bounds, that is Lemma 3.13 or (2.10), immediately gives that $\mathbf{P}(a \xrightarrow{r_0} u) \geq (1 - o(1)) V^{-1} \mathbb{E}|B(r_0)|$ for *most* vertices u (since $\sum_u \mathbf{P}(a \xrightarrow{r_0} u) = \mathbb{E}|B(r_0)|$). Had we had the same estimate for $\mathbf{P}_{A,B}(a \xrightarrow{r_0} u)$, the lower bound on the conditional first moment required to prove the estimate (2.11) would follow immediately. However, the probability $\mathbf{P}_{A,B}(a \xrightarrow{r_0} u)$ may heavily depend on the sets A and B .

To that aim, in Section 5 we present an intrinsic metric regularity theorem, similar in spirit to the extrinsic metric regularity theorem presented in [41]. Roughly, it states that for *most* sets A (more precisely, the weight of sets not having this is $o(\varepsilon)$) for which $B_x(r) = A$ satisfies $\partial B_x(r) \neq \emptyset$, we have that *most* vertices $a \in \partial A$ satisfy

$$\sum_u \mathbf{P}_A(a \xrightarrow{r_0} u) \geq (1 - o(1)) \mathbb{E}|B(r_0)|,$$

where \mathbf{P}_A is the conditional probability given $B_x(r) = A$. Thus, the expected size of the “future” of most vertices on the boundary is not affected by the conditioning on a typical “past”.

At this point comes another crucial application of the uniform connection bounds as in (2.10). Indeed, even if the expected “future” of a vertex has the same asymptotics with or without conditioning, we cannot a priori rule out the possibility that this conditional “future” concentrates on a small remote portion of the underlying graph G — this can potentially violate the concentration around the value in (2.11). However, our uniform connection bounds stated in Lemma 3.13 are robust enough to deal with conditioning and immediately imply that $\mathbf{P}_A(a \xrightarrow{r_0} u) = (1 - o(1)) V^{-1} \mathbb{E}|B(r_0)|$ for most a in ∂A and for most vertices u . In other words, not only did the conditioning not influence the size of the “future”, it also left its distribution approximately unaltered. These considerations allow us to give a lower bound of (2.11) on the conditional expectation. This and the conditional second moment calculation required to show concentration are performed in Section 6.

3. PRELIMINARIES

In this section we provide some preliminary results that we will use. These involve various expectations and probabilities related to the random variable $|\partial B(r)|$ in Section 3.2 and 3.3, non-backtracking random walks in Section 3.4 and its relation to uniform bounds for connection probabilities in Section 3.5. In Section 3.6 we use these results to prove part (a) of Theorem 1.3. Finally, in Section 3.7 we bound triangle and square diagrams. The results in this section do *not* rely on the assumptions of Theorem 1.3 but sometimes we do assume the finite triangle condition (1.5).

3.1. The “off” method and BK-Reimer inequality. We will frequently handle the events $\partial B(r) \neq \emptyset$ and $x \stackrel{=t}{\leftrightarrow} y$. These events are non-monotone with respect to adding edges; indeed, adding an edge may shorten a shortest path and prevent the events from holding. This non-monotonicity is a technical difficulty which unfortunately manifests itself in many of the arguments in this paper. Our main tools to deal with this problem are the BK-Reimer inequality [12, 52] and the notion of events occurring “off” a set of vertices. For the BK-Reimer inequality we use the formulation in [20].

For a subset of vertices A , we say that an event \mathcal{M} occurs *off* A , intuitively, if it occurs in $G_p \setminus A$. Formally, for a percolation configuration ω , we write ω_A for the configuration obtained from ω by turning all the edges touching A to closed. The event “ \mathcal{M} occurs off A ” is defined to be $\{\omega : \omega_A \in \mathcal{M}\}$. We also frequently write $\mathbf{P}_{\text{off } A}$ to denote the measure $\mathbf{P}_{\text{off } A}(\mathcal{M}) = \mathbf{P}_p(\mathcal{M} \text{ off } A)$. Equivalently, $\mathbf{P}_{\text{off } A}$ can be thought of as a percolation measure in which all edges touching A are closed with probability 1 and the rest are distributed independently as before. We often drop p from the notation when it is clear what p is. This framework also allows us to address the case when $A = A(\omega)$ is a *random* set measurable with respect to G_p (the most prominent example is $A = B_0(r)$). In this case, the event $\{\mathcal{M} \text{ occurs off } A(\omega)\}$ is defined to be

$$\{\mathcal{M} \text{ occurs off } A(\omega)\} = \{\omega : \omega_{A(\omega)} \in \mathcal{M}\}.$$

Let us review an example occurring frequently in our arguments in which \mathcal{M} is an arbitrary event and $A = B_x(s)$. In this case,

$$\mathbf{P}(\mathcal{M} \text{ off } B_x(s)) = \sum_A \mathbf{P}(B_x(s) = A) \mathbf{P}(\mathcal{M} \text{ off } A), \quad (3.1)$$

where we have used the fact that

$$\mathbf{P}(\mathcal{M} \text{ off } B_x(s) \mid B_x(s) = A) = \mathbf{P}(\mathcal{M} \text{ off } A),$$

since the events do not depend on edges touching A in both sides of the equation, and the marginal of the two distributions on the edges not touching A is the same product measure. In terms of this notation, for a subset of vertices A , we define

$$B_x^G(r; A) = \{y : d_{G_p}(x, y) \leq r \text{ off } A\}, \quad \partial B_x^G(r; A) = \{y : d_{G_p}(x, y) = r \text{ off } A\}$$

to be the intrinsic ball off A , and its boundary. We finally say that \mathcal{M} occurs *only on* A if \mathcal{M} occurs but \mathcal{M} off A does not occur. We frequently rely on the following inclusion:

Claim 3.1. *For any event \mathcal{M} and any subset of vertices $A \subset V$,*

$$\mathcal{M} \setminus \{\mathcal{M} \text{ only on } A\} \subset \{\mathcal{M} \text{ off } A\}.$$

Proof. By definition of “ \mathcal{M} only on A ” the event on the left hand side equals

$$\mathcal{M} \cap \{\mathcal{M}^c \cup \{\mathcal{M} \text{ off } A\}\}.$$

From this, it is easy to see that this event implies \mathcal{M} off A . □

Remark. Equality in Claim 3.1 does not hold (unless the right hand side is replaced by $\mathcal{M} \cap \{\mathcal{M} \text{ off } A\}$). This can easily be seen by taking a non-monotone event, say $\partial B_x(r) \neq \emptyset$.

The following lemmas are inequalities valid for any graph G and any p .

Lemma 3.2 (Disjoint survival). *For any graph G , $p \in [0, 1]$, vertices x, y, z and integers r, s ,*

$$\mathbf{P}(\partial B_x(r) \neq \emptyset, \partial B_y(s) \neq \emptyset, B_x(r) \cap B_y(s) = \emptyset) \leq \mathbf{P}(\partial B_x(r) \neq \emptyset) \max_{A \subset V} \mathbf{P}_{\text{off } A}(\partial B_y(s) \neq \emptyset).$$

Proof. We condition on $B_x(r) = A$ such that A satisfies $\partial B_x(r) \neq \emptyset$ and $\mathbf{P}(B_x(r) = A) > 0$. The left hand side is at most

$$\sum_{A: \partial B_x(r) \neq \emptyset} \mathbf{P}(B_x(r) = A) \mathbf{P}(\partial B_y(s) \neq \emptyset \text{ off } A),$$

as in (3.1). The lemma now follows. \square

Lemma 3.3. *For any graph G , $p \in [0, 1]$, vertices u, v and integers $r, \ell > 0$,*

$$\mathbf{P}(0 \xrightarrow{=r} u \text{ and } 0 \xleftarrow{\ell} v) \leq \sum_z \sum_{t=0}^r \mathbf{P}(0 \xrightarrow{=t} z) \mathbf{P}(z \xleftarrow{\ell} v) \max_{A \subset V} \mathbf{P}_{\text{off } A}(z \xrightarrow{=r-t} u).$$

Proof. We claim that if $0 \xrightarrow{=r} u$ and $0 \xleftarrow{\ell} v$, then there exist $z \in V$ and $t \leq r$ such that the two following events occur disjointly

- (a) There exists a shortest open path η of length r between 0 and u such that $\eta(t) = z$, and
- (b) There exist an open path between z and ℓ of length at most ℓ .

Indeed, if the event occurs, let η be the lexicographical first shortest path of length r between 0 and u and let γ be an open path of length at most ℓ between 0 and v . We take z to be the last vertex on γ which belongs to η and put t such that $\eta(t) = z$. The witness for the first event is the set of open edges of η together with all the closed edges in G_p (the closed edges determine that η is a shortest path) and the second witness is the edges of γ from z to v . These are disjoint witnesses so we may use the BK-Reimer inequality and bound

$$\mathbf{P}(0 \xrightarrow{=r} u \text{ and } 0 \xleftarrow{\ell} v) \leq \sum_{z \in V, t \leq r} \mathbf{P}((a)) \mathbf{P}(z \xleftarrow{\ell} v).$$

To bound $\mathbf{P}((a))$ we condition on $B_0(t) = A$ such that A satisfies $0 \xrightarrow{=t} z$, so

$$\mathbf{P}((a)) = \sum_{A: 0 \xrightarrow{=t} z} \mathbf{P}(B_0(t) = A) \mathbf{P}(z \xrightarrow{=r-t} u \text{ off } A),$$

and the lemma follows. \square

3.2. Survival probabilities. In this section, we prove Lemma 2.3 and a few other useful estimates of a similar nature. In the rest of this section we only rely on the finite triangle condition (1.5), Theorem 2.1 and Theorem 2.2 (both of which follow from the triangle condition, as shown in [39] and the Appendix).

Lemma 3.4 (Relating connection probabilities for different p 's). *Let $p_1, p_2 \in [0, 1]$ satisfy $p_1 \leq p_2$ and let $r > 0$ be integer. The following bounds hold for any graph G and vertex v :*

- (1) $\mathbf{P}_{p_2}(\partial B_v(r) \neq \emptyset) \leq \left(\frac{p_2}{p_1}\right)^r \mathbf{P}_{p_1}(\partial B_v(r) \neq \emptyset)$,
- (2) $\mathbb{E}_{p_2} |\partial B_v(r)| \leq \left(\frac{p_2}{p_1}\right)^r \mathbb{E}_{p_1} |\partial B_v(r)|$.

Proof. We recall the standard simultaneous coupling between percolation measure at different p 's discussed in Section 2.1. Order all the paths in G of length r starting at v lexicographically. Write \mathcal{A} for the event that $\partial B_v(r) \neq \emptyset$ in G_{p_2} and that the lexicographical first p_2 -open shortest path of length r starting at v is in fact p_1 -open. We claim that

$$\mathbf{P}(\mathcal{A}) = \left(\frac{p_1}{p_2}\right)^r \mathbf{P}(\partial B_v(r) \neq \emptyset \text{ in } G_{p_2}). \quad (3.2)$$

Indeed, conditioned on the edges of G_{p_2} , the value $U(e)$ of each edge in G_{p_2} is distributed uniformly on the interval $[0, p_2]$. Hence, the probability of the first shortest path being p_1 -open in this conditioning

is precisely $(p_1/p_2)^r$, which proves (3.2). To see (1), note that if the first p_2 -open shortest path is p_1 -open, then it is a shortest path of length r in G_{p_1} , so that \mathcal{A} implies that $\partial B_v(r) \neq \emptyset$ in G_{p_1} whence

$$\mathbf{P}_{p_1}(\partial B_v(r) \neq \emptyset) \geq \left(\frac{p_1}{p_2}\right)^r \mathbf{P}_{p_2}(\partial B_v(r) \neq \emptyset).$$

The proof of (2) is similar and we omit the details. \square

Corollary 3.5 (Correlation length is $1/\varepsilon$). *Let G be a transitive finite graph for which (1.5) holds and put $p = p_c(1 + \varepsilon)$. The following bounds hold for any subset of vertices A and any vertex v and any integer r :*

- (1) $\mathbf{P}_{\text{off } A}(\partial B_v(\varepsilon^{-1}) \neq \emptyset) = O(\varepsilon)$, and
- (2) $\mathbb{E}|B_v(r; A)| = O(r(1 + \varepsilon)^r)$.

Proof. The result is immediate by combining Lemma 3.4 and Theorem 2.1. \square

Remark. In Section 4 we will show a sharp estimate replacing (2) in the above corollary.

Lemma 3.6 (Supercritical survival probability). *Let G be a transitive finite graph for which (1.5) holds and put $p = p_c(1 + \varepsilon)$. Then, for any $M \rightarrow \infty$ and any subset of vertices A ,*

$$\mathbf{P}_{\text{off } A}(\partial B(M\varepsilon^{-1}) \neq \emptyset) \leq (2 + o(1))\varepsilon,$$

and, for any $M \leq \log \log(\varepsilon^3 V)$ such that $M \rightarrow \infty$,

$$\mathbf{P}(\partial B(M\varepsilon^{-1}) \neq \emptyset) \geq (2 - o(1))\varepsilon.$$

Proof. To prove the upper bound we write

$$\begin{aligned} \mathbf{P}_{\text{off } A}(\partial B(M\varepsilon^{-1}) \neq \emptyset) &= \mathbf{P}_{\text{off } A}(\partial B(M\varepsilon^{-1}) \neq \emptyset, |\mathcal{C}(0)| > \sqrt{M}\varepsilon^{-2}) \\ &\quad + \mathbf{P}_{\text{off } A}(\partial B(M\varepsilon^{-1}) \neq \emptyset, |\mathcal{C}(0)| \leq \sqrt{M}\varepsilon^{-2}). \end{aligned}$$

The first term on the right hand side is at most $(2 + o(1))\varepsilon$ by Theorem 2.2 — note that we used the fact that the event $|\mathcal{C}(0)| \geq k$ is monotone so $\mathbf{P}_{\text{off } A}(|\mathcal{C}(0)| \geq k) \leq \mathbf{P}(|\mathcal{C}(0)| \geq k)$. It remains to show that the second term is $o(\varepsilon)$. Indeed, if this event occurs, then there exists a radius $j \in [M\varepsilon^{-1}/3, 2M\varepsilon^{-1}/3]$ such that

$$0 < \partial B(j; A) \leq 3M^{-1/2}\varepsilon^{-1} \text{ and } \partial B(M\varepsilon^{-1}; A) \neq \emptyset.$$

Let J be the first level satisfying this. By Corollary 3.5 and the union bound

$$\mathbf{P}_{\text{off } A}(\exists y \in \partial B(J; A) \text{ with } \partial B_y(M\varepsilon^{-1}/3; A) \neq \emptyset \text{ off } B(J; A) \mid B(J; A)) \leq C\varepsilon |\partial B(J; A)| = O(M^{-1/2}).$$

Corollary 3.5 also shows that $\mathbf{P}_{\text{off } A}(\partial B(M\varepsilon^{-1}/3) \neq \emptyset) = O(\varepsilon)$, so putting this together gives

$$\mathbf{P}_{\text{off } A}(\partial B(M\varepsilon^{-1}) \neq \emptyset, |\mathcal{C}(x)| \leq \sqrt{M}\varepsilon^{-2}) = O(M^{-1/2}\varepsilon), \quad (3.3)$$

concluding the proof of the upper bound. For the lower bound, take $k_0 = \varepsilon^{-2}(\varepsilon^3 V)^\alpha$ for some fixed $\alpha \in (0, 1/3)$. We have

$$\begin{aligned} \mathbf{P}(\partial B(M\varepsilon^{-1}) \neq \emptyset) &\geq \mathbf{P}(\partial B(M\varepsilon^{-1}) \neq \emptyset \text{ and } |\mathcal{C}(0)| \geq k_0) \\ &= \mathbf{P}(|\mathcal{C}(0)| \geq k_0) - \mathbf{P}(|\mathcal{C}(0)| \geq k_0 \text{ and } \partial B(M\varepsilon^{-1}) = \emptyset), \end{aligned}$$

so by Theorem 2.2 it suffices to bound the last term on the right hand side from above. Indeed, by Markov's inequality and Corollary 3.5,

$$\begin{aligned} \mathbf{P}(|\mathcal{C}(0)| \geq k_0 \text{ and } \partial B(M\varepsilon^{-1}) = \emptyset) &\leq \mathbf{P}(|B(M\varepsilon^{-1})| \geq k_0) \\ &\leq \frac{CMe^M\varepsilon^{-1}}{k_0} = O\left(\varepsilon(\varepsilon^3 V)^{-\alpha} \log(\varepsilon^3 V)\right) = o(\varepsilon), \end{aligned} \quad (3.4)$$

since $M \leq \log \log(\varepsilon^3 V)$. \square

We proceed with preparations towards the proof of Lemma 2.3. For an integer $r > 0$, we write N_r for the random variable

$$N_r = |\{x: \partial B_x(r) \neq \emptyset\}|.$$

We think of $1/\varepsilon$ as the correlation length, see [27]. In other words, when $r \gg 1/\varepsilon$, then the vertices contributing to N_r should be those in the giant component.

Lemma 3.7 (N_r is concentrated). *Let G_m be a sequence of transitive finite graphs with degree m for which (1.5) holds and $m \rightarrow \infty$. Put $p = p_c(1 + \varepsilon)$, then for any $r \gg 1/\varepsilon$ satisfying $r \leq \varepsilon^{-1} \log \log(\varepsilon^3 V)$,*

$$\frac{N_r}{2\varepsilon V} \xrightarrow{\mathbb{P}} 1.$$

Proof. We use a second moment method on N_r . Lemma 3.6 and our assumption on r shows that

$$\mathbb{E}N_r = (2 + o(1))\varepsilon V.$$

The second moment is

$$\mathbb{E}N_r^2 = \sum_{x,y} \mathbf{P}(\partial B_x(r) \neq \emptyset \text{ and } \partial B_y(r) \neq \emptyset).$$

We have

$$\begin{aligned} \mathbf{P}(\partial B_x(r) \neq \emptyset \text{ and } \partial B_y(r) \neq \emptyset) &\leq \mathbf{P}(\partial B_x(r) \neq \emptyset \text{ and } \partial B_y(r) \neq \emptyset, B_x(r) \cap B_y(r) = \emptyset) \\ &\quad + \mathbf{P}(x \overset{2r}{\longleftrightarrow} y). \end{aligned}$$

We sum the first term on the right hand side using Lemmas 3.2 and 3.6 and the second term using Corollary 3.5. We get that

$$\mathbb{E}N_r^2 \leq (4 + o(1))\varepsilon^2 V^2 + O(Vr(1 + \varepsilon)^{2r}) = (1 + o(1))[\mathbb{E}N_r]^2,$$

since $Vr(1 + \varepsilon)^{2r} = o(\varepsilon^2 V^2)$ by our assumption on r and since $\varepsilon^3 V \rightarrow \infty$. The assertion of the lemma now follows by Chebychev's inequality. \square

Proof of Lemma 2.3. Take $M = M_m$ and r as in (2.7) and write

$$Z_{\geq k_0} = N_r + |\{x: \partial B_x(r) = \emptyset, |\mathcal{C}(x)| \geq k_0\}| - |\{x: \partial B_x(r) \neq \emptyset, |\mathcal{C}(x)| < k_0\}|.$$

By Lemma 3.7, $N_r/(2\varepsilon V) \xrightarrow{\mathbb{P}} 1$, so it suffices to show that the expectation of both remaining terms is $o(\varepsilon V)$. The expectation of the first term is

$$V\mathbf{P}(x: \partial B_x(r) = \emptyset, |\mathcal{C}(v)| \geq k_0) = o(\varepsilon V), \quad (3.5)$$

by (3.4). The expectation of the second term now must be $o(\varepsilon V)$ since both N_r and $Z_{\geq k_0}$ have mean $(2 + o(1))\varepsilon V$ by Theorem 2.2 and Lemma 3.6. This shows that $Z_{\geq k_0}/(2\varepsilon V) \xrightarrow{\mathbb{P}} 1$ as stated in Lemma 2.3.

To prove the upper bound on $\mathbb{E}|\mathcal{C}(0)|$ we write

$$\mathbb{E}|\mathcal{C}(0)| = \sum_y \mathbf{P}(0 \leftrightarrow y) = \sum_y \mathbf{P}(0 \overset{[0,2r]}{\longleftrightarrow} y) + \sum_y \mathbf{P}(0 \overset{[2r,\infty]}{\longleftrightarrow} y).$$

By Corollary 3.5,

$$\sum_y \mathbf{P}(0 \overset{[0,2r]}{\longleftrightarrow} y) = \mathbb{E}|B(2r)| \leq C\varepsilon^{-1} \log^3(\varepsilon^3 V) = o(\varepsilon^2 V), \quad (3.6)$$

since $\varepsilon^3 V \gg 1$. If $0 \overset{[2r,\infty]}{\longleftrightarrow} y$, then the event

$$\{\partial B_0(r) \neq \emptyset, \partial B_y(r) \neq \emptyset, B_0(r) \cap B_y(r) = \emptyset\},$$

occurs. Hence Lemmas 3.2 and 3.6 give that $\mathbf{P}(0 \overset{[2r,\infty]}{\longleftrightarrow} y) \leq (4 + o(1))\varepsilon^2$ and summing this over y gives the required upper bound on $\mathbb{E}|\mathcal{C}(0)|$. \square

3.3. Disjoint survival probabilities. In this section we show that for most pairs x, y the event $\mathcal{A}(x, y, r, r)$ occurs with probability asymptotic to $4\varepsilon^2$. The point is that r is chosen such that $r \gg \varepsilon^{-1}$, where ε^{-1} is the correlation length, but $r \ll \varepsilon^{-1} \log(\varepsilon^3 V)$ which is the order of the diameter of \mathcal{C}_1 (we do not prove the estimate on the diameter here, but it can be obtained using the techniques of this paper).

Lemma 3.8 (Number of pairs surviving disjointly). *Let G_m be a sequence of transitive finite graphs with degree m for which (1.5) holds and $m \rightarrow \infty$. Put $p = p_c(1 + \varepsilon)$, then for any $r \gg \varepsilon^{-1}$ satisfying $r \leq \varepsilon^{-1} \log \log(\varepsilon^3 V)$*

$$\frac{|\{x, y : \mathcal{A}(x, y, r, r) \text{ occurs}\}|}{(2\varepsilon V)^2} \xrightarrow{\mathbb{P}} 1.$$

Proof. Define

$$N_r^{(2)} = |\{x, y : \mathcal{A}(x, y, r, r) \text{ occurs}\}|.$$

Then,

$$N_r^2 - |\{x, y : x \xleftrightarrow{2r} y\}| \leq N_r^{(2)} \leq N_r^2,$$

and $\mathbb{E}|\{x, y : x \xleftrightarrow{2r} y\}| = o(\varepsilon^2 V^2)$ as we did in (3.6). The result now follows by Markov's inequality and Lemma 3.7. \square

Lemma 3.9 (Most pairs have almost independent disjoint survival probabilities). *Let G_m be a sequence of transitive finite graphs with degree m for which (1.5) holds and $m \rightarrow \infty$. Put $p = p_c(1 + \varepsilon)$. Then, for any $j_x, j_y \leq \varepsilon^{-1} \log \log \varepsilon^3 V$ such that $j_x, j_y \gg \varepsilon^{-1}$, there exist at least $(1 - o(1))V^2$ pairs of vertices x, y such that*

$$\mathbf{P}(\mathcal{A}(x, y, j_x, j_y)) = (1 + o(1))4\varepsilon^2.$$

Proof. The upper bound $\mathbf{P}(\mathcal{A}(x, y, j_x, j_x)) \leq (1 + o(1))4\varepsilon^2$ follows immediately from Lemmas 3.2 and 3.6 and is valid for all pairs x, y . We turn to showing the corresponding lower bound. First, the inequality $\mathbb{E}[N_r^2] \geq (\mathbb{E}N_r)^2$ can be written as

$$\sum_{x, y} \mathbf{P}(\partial B_x(r) \neq \emptyset \text{ and } \partial B_y(r) \neq \emptyset) \geq V^2 \mathbf{P}(\partial B(r) \neq \emptyset)^2.$$

We take $r = \varepsilon^{-1} \log \log \varepsilon^3 V$. Since $\mathbf{P}(\partial B_x(j) \neq \emptyset)$ is decreasing in j , by Lemma 3.6 and our assumption on j_x and j_y we get

$$\sum_{x, y} \mathbf{P}(\partial B_x(j_x) \neq \emptyset \text{ and } \partial B_y(j_y) \neq \emptyset) \geq (4 - o(1))V^2 \varepsilon^2.$$

Secondly, Corollary 3.5 implies that

$$\sum_{x, y} \mathbf{P}(x \xleftrightarrow{2r} y) = V \mathbb{E}[|B(2r)|] \leq CVr(1 + \varepsilon)^{2r} = o(\varepsilon^2 V^2),$$

by our choice of r and since $\varepsilon^3 V \rightarrow \infty$. Since

$$\mathcal{A}(x, y, j_x, j_y) \subseteq \{\partial B_x(j_x) \neq \emptyset, \partial B_y(j_y) \neq \emptyset\} \setminus \{x \xleftrightarrow{2r} y\},$$

we deduce that

$$\sum_{x, y} \mathbf{P}(\mathcal{A}(x, y, j_x, j_y)) \geq (4 - o(1))\varepsilon^2 V^2,$$

and since the upper bound was valid for all x, y , the lemma follows. \square

Lemma 3.10. *Let G_m be a sequence of transitive finite graphs with degree m for which (1.5) holds and $m \rightarrow \infty$. Put $p = p_c(1 + \varepsilon)$. Then for any $r \leq \varepsilon^{-1} \log \log \varepsilon^3 V$ such that $r \gg \varepsilon^{-1}$ we have*

$$\frac{|\{x, y : \mathcal{A}(x, y, r, r) \text{ and } |\mathcal{C}(x)| \leq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}\}|}{(\varepsilon V)^2} \xrightarrow{\mathbb{P}} 0.$$

Proof. By Lemma 3.7, the assertion follows from the statement that

$$|\{x: \partial B_x(r) \neq \emptyset \text{ and } |\mathcal{C}(x)| \leq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}\}| / (\varepsilon V) \xrightarrow{\mathbb{P}} 0.$$

To show this, note that

$$\mathbf{P}(\partial B_x(r) = \emptyset \text{ and } |\mathcal{C}(x)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}) \leq \mathbf{P}(|B_x(r)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}) \leq \frac{Cr(1+\varepsilon)^r}{(\varepsilon^3 V)^{1/4} \varepsilon^{-2}} = o(\varepsilon).$$

Hence, by Theorem 2.2,

$$\mathbf{P}(\partial B_x(r) \neq \emptyset \text{ and } |\mathcal{C}(x)| \geq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}) \geq (2 - o(1))\varepsilon.$$

Together with Lemma 3.6, this yields that

$$\mathbf{P}(\partial B_x(r) \neq \emptyset \text{ and } |\mathcal{C}(x)| \leq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}) = o(\varepsilon),$$

concluding our proof. \square

3.4. Using the non-backtracking random walk. In the rest of this section we provide several basic percolation estimates which we use throughout the paper. These include bounds on long and short connection probabilities and bounds on various triangle and square diagrams. It is here that we make crucial use of the geometry of the graph and the behavior of the random walk on it, namely, the assumptions of Theorem 1.3. We frequently use *non-backtracking* random walk estimates. This walk is a simple random walk on a graph that is not allowed to traverse back on an edge it has just walked on. Let us first define it formally.

The non-backtracking random walk on an undirected graph $G = (V, E)$, starting from a vertex $x \in V$, is a Markov chain $\{X_t\}$ with transition matrix \mathbf{P}^x on the state space of *directed edges*

$$\vec{E} = \{(x, y) : \{x, y\} \in E\}.$$

If $X_t = (x, y)$, then we write $X_t^{(1)} = x$ and $X_t^{(2)} = y$. Also, for notational convenience, we write

$$\mathbf{P}_{(x,w)}(\cdot) = \mathbf{P}^x(\cdot | X_0 = (x, w)), \quad \text{and} \quad \mathbf{p}^t(x, y) = \mathbf{P}^x(X_t^{(2)} = y).$$

The non-backtracking walk starting from a vertex x has initial state given by

$$\mathbf{P}^x(X_0 = (x, y)) = \mathbf{1}_{\{(x,y) \in \vec{E}\}} \frac{1}{\deg(x)},$$

and transition probabilities given by

$$\mathbf{P}_{(u,v)}(X_1 = (v, w)) = \mathbf{1}_{\{(v,w) \in \vec{E}, w \neq u\}} \frac{1}{\deg(v) - 1},$$

where we write $\deg(x)$ for the degree of x in G . The following lemma will be useful.

Lemma 3.11. *Let G be a regular graph of degree m . Then, for $t \geq 0$,*

$$\sum_u \mathbf{p}^1(0, u) \mathbf{p}^t(u, z) = \mathbf{p}^{t+1}(0, z) + \frac{1}{m-1} \mathbf{p}^{t-1}(0, z),$$

with the convention that $\mathbf{p}^{-1}(0, z) = 0$.

Proof. The claim follows by conditioning on whether the first step of the NBW counted in $\mathbf{p}^t(u, z)$ is equal to $(u, 0)$ or not. We omit further details. \square

3.5. Uniform upper bounds on long connection probabilities. In this section we show that long percolation paths are asymptotically equally likely to end at any vertex in G .

Lemma 3.12. *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Then, for any integer $t \geq m_0$ and any vertex x ,*

$$\mathbf{P}_p(0 \overset{=t}{\longleftrightarrow} x) + \mathbf{P}_p(0 \overset{=t+1}{\longleftrightarrow} x) \leq \frac{2 + O(\alpha_V + \varepsilon m_0)}{V} \mathbb{E}|\partial B(t - m_0)|.$$

Proof. If $0 \overset{=t}{\longleftrightarrow} x$, then there exists a vertex v and a simple path ω of length m_0 from x to v such that the event

$$\{\omega \text{ is open}\} \circ \{v \overset{=t-m_0}{\longleftrightarrow} x\}$$

occurs. Indeed, consider a shortest path η of length t between 0 to x . Take $v = \eta(m_0)$ and $\omega = \eta[1, m_0]$. Now, the first witness is the path ω and the witness for $\{v \overset{=t-m_0}{\longleftrightarrow} x\}$ is the path $\eta[m_0, t]$ together with all the closed edges in G_p (which determine that $\eta[m_0, t]$ is a shortest path). These are disjoint witnesses. If $0 \overset{=t+1}{\longleftrightarrow} x$ occurs, then we get the same conclusion with ω of length $m_0 + 1$. We now apply the BK-Reimer inequality and the fact that the probability that ω is open is precisely $p^{|\omega|}$. This yields

$$\mathbf{P}_p(0 \overset{=t}{\longleftrightarrow} x) \leq p^{m_0} \sum_v \sum_{\substack{\omega: |\omega|=m_0 \\ \omega[m_0]=v}} \mathbf{P}_p(v \overset{=t-m_0}{\longleftrightarrow} x),$$

and

$$\mathbf{P}_p(0 \overset{=t+1}{\longleftrightarrow} x) \leq p^{m_0+1} \sum_v \sum_{\substack{\omega: |\omega|=m_0+1 \\ \omega[m_0+1]=v}} \mathbf{P}_p(v \overset{=t-m_0}{\longleftrightarrow} x).$$

We now bound these above by relaxing the requirement that ω is simple and only requiring that it is non-backtracking. Since $m_0 = T_{\text{mix}}(\alpha_V)$, we get by definition that

$$\frac{|\{\omega: |\omega| = m_0, \omega[m_0] = v\}|}{m(m-1)^{m_0-1}} + \frac{|\{\omega: |\omega| = m_0 + 1, \omega[m_0 + 1] = v\}|}{m(m-1)^{m_0}} = \mathbf{p}^{m_0}(0, v) + \mathbf{p}^{m_0+1}(0, v) \leq \frac{2 + 2\alpha_V}{V},$$

where we enumerated only non-backtracking paths in the above. Using this, condition (2) and summing over v gives

$$\begin{aligned} \mathbf{P}_p(0 \overset{=t}{\longleftrightarrow} x) + \mathbf{P}_p(0 \overset{=t+1}{\longleftrightarrow} x) &\leq \frac{2 + O(\alpha_V)}{V} [p(m-1)]^{m_0} \mathbb{E}|\partial B(t - m_0)| \\ &\leq \frac{2 + O(\alpha_V + \varepsilon m_0)}{V} \mathbb{E}|\partial B(t - m_0)|, \end{aligned}$$

concluding our proof. \square

Lemma 3.13. *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Then, for any $r \geq m_0$ and any vertex x ,*

$$\mathbf{P}_p(0 \overset{P[m_0, r]}{\longleftrightarrow} x) \leq \frac{1 + O(\alpha_V + \varepsilon m_0)}{V} \mathbb{E}|B(r)|.$$

Proof. The proof is similar to that of Lemma 3.12. If the event occurs, then there exists a vertex v and a simple path ω of length m_0 from 0 to v such that the event

$$\{\omega \text{ is open}\} \circ \{v \overset{r}{\longleftrightarrow} x\},$$

occurs. Hence,

$$\mathbf{P}_p(0 \overset{P[m_0, r]}{\longleftrightarrow} x) \leq p^{m_0} \sum_v \sum_{\substack{\omega: |\omega|=m_0 \\ \omega[m_0]=v}} \mathbf{P}_p(v \overset{r}{\longleftrightarrow} x),$$

by the BK inequality. By the same argument,

$$\mathbf{P}_p(0 \xleftrightarrow{P[m_0, r]} x) \leq p^{m_0+1} \sum_v \sum_{\substack{\omega: |\omega|=m_0+1 \\ \omega[m_0+1]=v}} \mathbf{P}_p(v \xleftrightarrow{r} x).$$

The reason we make two such similar estimates is that due to possible periodicity, in each of the estimates the sum over v may be 0 on half the vertices. We now take the average of these two estimates, sum over v to get the $\mathbb{E}|B(r)|$ factor and use the same analysis as in Lemma 3.12 using condition (2). This gives the required assertion of the lemma. \square

Lemma 3.14. *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Then, for any $r \geq m_0$ and any vertex x ,*

$$\mathbf{P}(0 \xleftrightarrow{[r, 2r]} x) \leq \frac{1 + O(\alpha_V + \varepsilon m_0)}{V} \mathbb{E}|B([r - m_0, 2r - m_0])|.$$

Proof. This follows by summing the estimate of Lemma 3.12 and using the fact that

$$\mathbb{E}|\partial B(t)| \leq p(m-1)\mathbb{E}|\partial B(t-1)| \leq (1 + m^{-1} + \varepsilon)\mathbb{E}|\partial B(t-1)|,$$

where the last inequality is due to condition (2) and the first inequality holds since, given $\partial B(t-1)$, $|\partial B(t)|$ is stochastically bounded above by a sum of $|\partial B(t-1)|$ binomial random variables with parameters $m-1$ and p . The lemma follows since $\alpha_V \geq m^{-1}$. \square

We close this section with a remark which will become useful later. We often would like to have these uniform connection bounds off some subsets of vertices. The proofs in the lemmas of this section immediately generalize to such a setting. This is because the claim “the number of paths from 0 to v of length m_0 is at most n ” still holds even if we are in $G \setminus A$, for any subset of vertices A . We state the required assertion here and omit their proofs:

Lemma 3.15 (Uniform connection bounds off sets). *Consider percolation on $G = \{0, 1\}^m$ with $p = p_c(1 + \varepsilon)$, and let A be any subset of vertices. Then, for any $r \geq m_0$ and any vertex x ,*

$$\begin{aligned} \mathbf{P}_{\text{off } A}(0 \xleftrightarrow{=r} x) &\leq (2 + O(\alpha_V + \varepsilon m_0)) V^{-1} \mathbb{E}|\partial B(r - m_0; A)|, \\ \mathbf{P}_{\text{off } A}(0 \xleftrightarrow{[m_0, r]} x) &\leq (1 + O(\alpha_V + \varepsilon m_0)) V^{-1} \mathbb{E}|B(r; A)|. \end{aligned}$$

3.6. Proof of part (a) of Theorem 1.3. We demonstrate the use of Lemma 3.13 by showing that the finite triangle condition holds under the assumptions of Theorem 1.3. We begin with an easy calculation.

Claim 3.16. *On any regular graph G of degree m and any vertices x, y ,*

$$\sum_{u, v} \sum_{t_1, t_2, t_3: t_1+t_2+t_3 \in \{0, 1, 2\}} \mathbf{p}^{t_1}(x, u) \mathbf{p}^{t_2}(u, v) \mathbf{p}^{t_3}(v, y) = \mathbf{1}_{\{x=y\}} + O(m^{-1}),$$

and

$$\sum_{u, v} \sum_{t_1, t_2, t_3: t_1+t_2+t_3 \in \{1, 2\}} \mathbf{p}^{t_1}(x, u) \mathbf{p}^{t_2}(u, v) \mathbf{p}^{t_3}(v, y) = O(m^{-1}).$$

Proof. We prove both statements simultaneously. The contribution coming from $t_1 + t_2 + t_3 = 0$ is the one we get when $x = u = v = y$ giving $\mathbf{1}_{\{x=y\}}$. The contributions coming from $t_1 + t_2 + t_3 = 1$ can only come from the cases $u = v = y$ and $(t_1, t_2, t_3) = (1, 0, 0)$, or $u = v = x$ and $(t_1, t_2, t_3) = (0, 0, 1)$, or $u = x$ and $v = y$ and $(t_1, t_2, t_3) = (0, 1, 0)$. These are easily bounded using the fact that $\max_z \mathbf{p}^t(u, z) \leq 1/(m-1)$ for any $t \geq 1$. We perform a similar case analysis to bound the contributions of $t_1 + t_2 + t_3 = 2$. If $(t_1, t_2, t_3) = (0, 0, 2)$, then we must have $u = v = x$ and $\mathbf{p}^2(v, y) = O(m^{-1})$; this argument also handles the case where one of the other t_i 's is 2. In the case $(t_1, t_2, t_3) = (1, 1, 0)$ we must have that $v = y$ and that u is a neighbor both of x and y . There are at most m such u 's and for each we have that $\mathbf{p}^1(x, u) \mathbf{p}^1(u, y) = O(m^{-2})$. The cases $(t_1, t_2, t_3) \in \{(0, 1, 1), (1, 0, 1)\}$ are handled similarly. \square

Proof of part (a) of Theorem 1.3. Let $p \leq p_c$. If one of the connections in the sum $\nabla_p(x, y)$ is of length in $[m_0, \infty)$, say between x and u , then we may estimate

$$\begin{aligned} \sum_{u,v} \mathbf{P}_p(x \xleftrightarrow{[m_0, \infty)} u) \mathbf{P}_p(u \leftrightarrow v) \mathbf{P}_p(v \leftrightarrow y) &\leq \frac{(1 + o(1)) \mathbb{E}_p |\mathcal{C}(0)|}{V} \sum_{u,v} \mathbf{P}_p(u \leftrightarrow v) \mathbf{P}_p(v \leftrightarrow y) \\ &= \frac{(1 + o(1)) (\mathbb{E}_p |\mathcal{C}(0)|)^3}{V}, \end{aligned}$$

where we used Lemma 3.13 (and took $r \rightarrow \infty$ in both sides of the lemma) for the first inequality. Thus, we are only left to deal with short connections,

$$\nabla_p(x, y) \leq \sum_{u,v} \mathbf{P}_p(x \xleftrightarrow{m_0} u) \mathbf{P}_p(u \xleftrightarrow{m_0} v) \mathbf{P}_p(v \xleftrightarrow{m_0} y) + O(V^{-1} \chi(p)^3).$$

We write

$$\mathbf{P}_p(x \xleftrightarrow{m_0} u) = \sum_{t_1=0}^{m_0} \mathbf{P}_p(x \xleftrightarrow{t_1} u),$$

and do the same for all three terms so that

$$\nabla_p(x, y) \leq \sum_{u,v} \sum_{t_1, t_2, t_3}^{m_0} \mathbf{P}_p(x \xleftrightarrow{t_1} u) \mathbf{P}_p(u \xleftrightarrow{t_2} v) \mathbf{P}_p(v \xleftrightarrow{t_3} y) + O(V^{-1} \chi(p)^3). \quad (3.7)$$

We bound

$$\mathbf{P}_p(x \xleftrightarrow{t_1} u) \leq m(m-1)^{t_1-1} \mathbf{p}^{t_1}(x, u) p^{t_1},$$

simply because $m(m-1)^{t_1-1} \mathbf{p}^{t_1}(x, u)$ is an upper bound on the number of simple paths of length t_1 starting at x and ending at u . Hence

$$\nabla_p(x, y) \leq \frac{m^3}{(m-1)^3} \sum_{u,v} \sum_{t_1, t_2, t_3}^{m_0} [p(m-1)]^{t_1+t_2+t_3} \mathbf{p}^{t_1}(x, u) \mathbf{p}^{t_2}(u, v) \mathbf{p}^{t_3}(v, y) + O(V^{-1} \chi(p)^3).$$

Since $p \leq p_c$, assumption (2) gives that $[p(m-1)]^{t_1+t_2+t_3} = 1 + O(\alpha_V)$, and condition (3) together with Claim 3.16 yields that

$$\nabla_p(x, y) \leq \mathbf{1}_{\{x=y\}} + O(V^{-1} \chi(p)^3) + O(m^{-1} + \alpha_V / \log V),$$

concluding the proof. \square

3.7. Restricted triangle and square diagrams. In this section, we provide several extensions to the triangle condition (1.5). We will bound the triangle diagram in the supercritical phase (which requires a bound on the length of connections, otherwise the sums blow up) and estimate a square diagram which will be useful in a key second moment calculation in Section 6.

Lemma 3.17 (Short supercritical triangles). *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Then,*

$$\max_{x,y} \sum_{u,v: \{u,v\} \neq \{0,0\}} \mathbf{P}_p(x \xleftrightarrow{m_0} u) \mathbf{P}_p(u \xleftrightarrow{m_0} v) \mathbf{P}_p(v \xleftrightarrow{m_0} y) = O(\alpha_V + \varepsilon m_0).$$

Proof. This follows immediately by assumptions (2) and (3) of Theorem 1.3 and the usual bound

$$\mathbf{P}_p(x \xleftrightarrow{s} u) \leq p^s m(m-1)^{s-1} \mathbf{p}^s(x, u),$$

as we did before. \square

FIGURE 1. A square diagram.

Corollary 3.18 (Long supercritical triangles). *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Let r_1, r_2, r_3 be integers that are all at least m_0 . Then,*

$$\begin{aligned} \max_{x,y} \sum_{u,v: \{u,v\} \neq \{x,y\}} \mathbf{P}(x \overset{r_1}{\longleftrightarrow} u) \mathbf{P}(u \overset{r_2}{\longleftrightarrow} v) \mathbf{P}(v \overset{r_3}{\longleftrightarrow} y) \\ \leq O(\alpha_V + \varepsilon m_0) + \frac{(3 + O(\alpha_V + \varepsilon m_0))}{V} \mathbb{E}|B(r_1)| \mathbb{E}|B(r_2)| \mathbb{E}|B(r_3)|. \end{aligned} \quad (3.8)$$

Proof. We split the sum into two cases. The first case is that at least one of the connection events occurs with a path of length at least m_0 . For instance, if $x \overset{P[m_0, r_1]}{\longleftrightarrow} u$ occurs, then we use Lemma 3.13 to bound, uniformly in x, y ,

$$\begin{aligned} \sum_{u,v} \mathbf{P}(x \overset{P[m_0, r_1]}{\longleftrightarrow} u) \mathbf{P}(u \overset{r_2}{\longleftrightarrow} v) \mathbf{P}(v \overset{r_3}{\longleftrightarrow} y) \\ \leq \frac{(1 + O(\alpha_V + \varepsilon m_0))}{V} \mathbb{E}|B(r_1)| \sum_{u,v} \mathbf{P}(u \overset{r_2}{\longleftrightarrow} v) \mathbf{P}(v \overset{r_3}{\longleftrightarrow} y) \\ = \frac{(1 + O(\alpha_V + \varepsilon m_0))}{V} \mathbb{E}|B(r_1)| \mathbb{E}|B(r_2)| \mathbb{E}|B(r_3)|. \end{aligned}$$

The second case is when all the connections occur with paths of length at most m_0 , in which case we use Lemma 3.17 and get a $O(\alpha_V + \varepsilon m_0)$ bound. This concludes the proof. \square

Lemma 3.19 (Supercritical square diagram). *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Let r_1, r_2 be both at least m_0 . Then,*

$$\sum_{(u_1, u_1'), (u_2, u_2'), z_1, z_2} \mathbf{P}(z_1 \overset{r_1}{\longleftrightarrow} u_1) \mathbf{P}(z_1 \overset{r_1}{\longleftrightarrow} u_2) \mathbf{P}(z_2 \overset{r_2}{\longleftrightarrow} u_1') \mathbf{P}(z_2 \overset{r_2}{\longleftrightarrow} u_2') \leq C m^2 (\mathbb{E}|B(r_1)|)^2 (\mathbb{E}|B(r_2)|)^2 + C V m^2 m_0 \alpha_V.$$

Proof. See Figure 1. If one of the connections is of length at least m_0 , then we use Lemma 3.13 and the summation simplifies. For instance, if $u_1 \overset{[m_0, r_1]}{\longleftrightarrow} z_1$, then we use Lemma 3.13 and sum over z_1 , followed by sums over u_1 and u_2 . This gives a bound of

$$\frac{C m^2 (\mathbb{E}|B(r_1)|)^2}{V} \sum_{u_1', u_2', z_2} \mathbf{P}(z_2 \overset{r_2}{\longleftrightarrow} u_1') \mathbf{P}(z_2 \overset{r_2}{\longleftrightarrow} u_2') \leq C m^2 [\mathbb{E}|B(r_1)|^2 \mathbb{E}|B(r_2)|^2],$$

where $C > 1$ is an upper bound on $1 + O(\alpha_V + \varepsilon m_0)$.

We are left to bound the sum

$$\begin{aligned} \sum_{(u_1, u_1'), (u_2, u_2'), z_1, z_2} \mathbf{P}(z_1 \overset{m_0}{\longleftrightarrow} u_1) \mathbf{P}(z_1 \overset{m_0}{\longleftrightarrow} u_2) \mathbf{P}(z_2 \overset{m_0}{\longleftrightarrow} u_1') \mathbf{P}(z_2 \overset{m_0}{\longleftrightarrow} u_2') \\ = V \sum_{(u_1, u_1'), (u_2, u_2'), z_2} \mathbf{P}(0 \overset{m_0}{\longleftrightarrow} u_1) \mathbf{P}(0 \overset{m_0}{\longleftrightarrow} u_2) \mathbf{P}(z_2 \overset{m_0}{\longleftrightarrow} u_1') \mathbf{P}(z_2 \overset{m_0}{\longleftrightarrow} u_2'), \end{aligned} \quad (3.9)$$

by transitivity. We write this sum as $V \sum_{u'_2} f(u'_2)g(u'_2)$, where

$$g(u'_2) = \sum_{(u_1, u'_1), z_2} \mathbf{P}(0 \xleftrightarrow{m_0} u_1) \mathbf{P}(z_2 \xleftrightarrow{m_0} u'_1) \mathbf{P}(z_2 \xleftrightarrow{m_0} u'_2), \quad f(u'_2) = \sum_{u_2 \sim u'_2} \mathbf{P}(0 \xleftrightarrow{m_0} u_2). \quad (3.10)$$

We then bound

$$\begin{aligned} V \sum_{u'_2} f(u'_2)g(u'_2) &\leq V \left(\sum_{u'_2} f(u'_2) \right) \left(\max_{u'_2} g(u'_2) \right) \\ &= V m \mathbb{E}|B(m_0)| \max_x \sum_{(u_1, u'_1), z_2} \mathbf{P}(0 \xleftrightarrow{m_0} u_1) \mathbf{P}(z_2 \xleftrightarrow{m_0} u'_1) \mathbf{P}(z_2 \xleftrightarrow{m_0} x). \end{aligned} \quad (3.11)$$

By condition (2) in Theorem 1.3, we can write the above as

$$\begin{aligned} V \sum_{u'_2} f(u'_2)g(u'_2) &\leq CV m^2 \mathbb{E}|B(m_0)| \max_x \sum_{u_1, u'_1, z_2} \sum_{t_1, t_2, t_3 \geq 0} \mathbf{p}^{t_1}(0, u_1) \mathbf{p}^1(u_1, u'_1) \mathbf{p}^{t_2}(u'_1, z_2) \mathbf{p}^{t_3}(z_2, x) \\ &\leq CV m^2 \mathbb{E}|B(m_0)| \max_x \sum_{u_1, z_2} \sum_{t_1, t_2, t_3 \geq 0} \mathbf{p}^{t_1}(0, u_1) [\mathbf{p}^{t_2+1}(u_1, z_2) + \frac{1}{m-1} \mathbf{p}^{t_2-1}(u_1, z_2)] \mathbf{p}^{t_3}(z_2, x) \\ &\leq CV m^2 \mathbb{E}|B(m_0)| (\alpha_V + O(1/m)) \leq CV m^2 \mathbb{E}|B(m_0)| \alpha_V, \end{aligned} \quad (3.12)$$

where we use Lemma 3.11 in the second inequality, and Claim 3.16, condition (2) in Theorem 1.3 and $\alpha_V \geq 1/m$ in the final inequality. Further, $\mathbb{E}|B(m_0)| = O(m_0)$ by Corollary 3.5 and the fact that $m_0 = o(\varepsilon^{-1})$. This concludes our proof. \square

4. VOLUME ESTIMATES

In this section, we study the expected volume of intrinsic balls and their boundaries at various radii in both the critical and supercritical phase.

4.1. In the critical regime. Given a subset of vertices A and integer $r \geq 0$ we write

$$G(r; A) = \mathbb{E}|\partial B(r; A)|, \quad G(r) = \max_{A \subseteq V(G)} G(r; A).$$

Theorem 2.1 implies that for “most” r ’s the value $G(r)$ is bounded above by a constant (more precisely, given any fixed A and R , the number of r ’s satisfying $1 \leq r \leq R$ and $\mathbb{E}|\partial B(r; A)| \geq C/\delta$ is at most δR). The following useful result states that $G(r)$ is at most a constant *for all* r . We believe that this estimate should hold only under the assumption of the triangle condition but we are only able to prove it under the stronger assumptions of Theorem 1.3.

Theorem 4.1 (Expected boundary size). *Let G be a graph satisfying the assumptions of Theorem 1.3 and consider percolation on it with $p = p_c$. Then there exists a constant $C > 0$ such that for any integer r ,*

$$G(r) \leq C.$$

Proof. Define $F(r) = \mathbb{E}|B(r)|$ and $F(r; A) = \mathbb{E}|B(r; A)|$, so that $F(r; A) \leq F(r)$ for all subsets A . Define $G^*(r) = \max_{s \leq r} G(s)$, and let $r \geq 2m_0$ be a maximizer of G^* , that is, r is such that $G(r') \leq G(r)$ for any $r' < r$. Let $A = A(r)$ be the subset of vertices which maximizes $G(r; A)$ so that $G(r; A) = G(r) = G^*(r)$. Given such r and $A = A(r)$ we will prove that there exists $c > 0$ such that for any integer $s \geq 0$,

$$F(r+s; A) \geq c G^*(r) F(s; A). \quad (4.1)$$

We begin by bounding

$$F(r+s; A) \geq \sum_v \mathbf{P}_{\text{off } A}(0 \xleftrightarrow{(r, r+s)} v).$$

For a vertex u we define $\mathcal{C}^u(0; A) = \{x : 0 \leftrightarrow x \text{ off } A \cup \{u\}\}$. Now, for any vertex v , if there exists $u \neq v$ such that $0 \overset{r}{\leftrightarrow} u$ off A and $u \overset{s}{\leftrightarrow} v$ off $\mathcal{C}^u(0; A)$, then $0 \overset{(r,r+s)}{\leftrightarrow} v$ off A . Furthermore, if such u exists, then it is unique because otherwise $v \in \mathcal{C}^u(0; A)$. We deduce that

$$F(r+s; A) \geq \sum_{v \neq u} \mathbf{P}_{\text{off } A}(0 \overset{r}{\leftrightarrow} u \text{ and } \{u \overset{s}{\leftrightarrow} v \text{ off } \mathcal{C}^u(0; A)\}).$$

We now condition on $\mathcal{C}^u(0; A) = H$ for some admissible H (that is, for which the probability of the event $\mathcal{C}^u(0; A) = H$ is positive, and in which $0 \overset{r}{\leftrightarrow} u$ occurs). In this conditioning, we also condition on the status of all edges touching H . Note that by definition $A \cap H = \emptyset$. We can write the right hand side of the last inequality as

$$\sum_{v \neq u} \sum_{H: 0 \overset{r}{\leftrightarrow} u \text{ off } A} \mathbf{P}_{\text{off } A}(\mathcal{C}^u(0; A) = H) \mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} v \text{ off } H),$$

in the same way as we derived (3.1). This can be rewritten as

$$\sum_{v \neq u} \sum_{H: 0 \overset{r}{\leftrightarrow} u \text{ off } A} \mathbf{P}_{\text{off } A}(\mathcal{C}^u(0; A) = H) [\mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} v) - \mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} v \text{ only on } H)].$$

We open the parenthesis and have that the first part of this sum equals precisely $G^*(r)F(s; A)$ since r and A were maximizers. We need to show that the second part of the sum is of lower order. To that aim, if $u \overset{s}{\leftrightarrow} v$ only on H , then there exists $h \in H$ such that $h \neq u$ and $\{u \overset{s}{\leftrightarrow} h\} \circ \{h \overset{s}{\leftrightarrow} v\}$. By the BK inequality, we bound the second part of the sum above by

$$\sum_u \sum_{H: 0 \overset{r}{\leftrightarrow} u \text{ off } A} \sum_{h \in H, h \neq u, v} \mathbf{P}_{\text{off } A}(\mathcal{C}^u(0; A) = H) \mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} h) \mathbf{P}_{\text{off } A}(h \overset{s}{\leftrightarrow} v).$$

Summing over v and changing the order of the summation gives that the last sum is at most

$$F(s; A) \sum_{u \neq h} \mathbf{P}_{\text{off } A}(0 \overset{r}{\leftrightarrow} u, 0 \leftrightarrow h) \mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} h).$$

We bound this from above using Lemma 3.3 by

$$F(s; A) \sum_{u \neq h, z \leq r} \sum \mathbf{P}_{\text{off } A}(0 \overset{t}{\leftrightarrow} z) \max_{D \subseteq V(G)} \mathbf{P}(z \overset{r-t}{\leftrightarrow} u \text{ off } A \cup D) \mathbf{P}_{\text{off } A}(z \leftrightarrow h) \mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} h). \quad (4.2)$$

We sum this separately for $t \leq r - m_0$ and $t \in [r - m_0, r]$. For $t \leq r - m_0$, we bound for any $D \subset V$

$$\mathbf{P}(z \overset{r-t}{\leftrightarrow} u \text{ off } A \cup D) \leq \frac{3G(r-t-m_0; A \cup D)}{V} \leq \frac{3G^*(r)}{V},$$

where the first inequality is by Lemma 3.15 and the second by definition of $G^*(r)$. Hence, the sum over $t \leq r - m_0$ in (4.2) is at most

$$\frac{3G^*(r)F(s; A)}{V} \sum_{u, h, z} \mathbf{P}_{\text{off } A}(0 \overset{r}{\leftrightarrow} z) \mathbf{P}_{\text{off } A}(z \leftrightarrow h) \mathbf{P}_{\text{off } A}(h \overset{s}{\leftrightarrow} u) \leq \frac{3G^*(r)F(s; A)(\mathbb{E}|\mathcal{C}(0)|)^3}{V} = 3\lambda^3 G^*(r)F(s; A),$$

where the inequality we got by summing over u, h and z (in that order) and the equality is due to the definition of p_c in (1.1). Our $\lambda = 1/10$ is chosen small enough so that $3\lambda^3 \leq 1/2$.

We now bound the sum in (4.2) for $t \in [r - m_0, r]$. We first bound

$$\mathbf{P}_{\text{off } A}(0 \overset{t}{\leftrightarrow} z) \leq \frac{3G^*(r)}{V},$$

as we did before using Lemma 3.15 and pull that term out of the sum. This gives an upper bound of

$$\frac{3G^*(r)F(s; A)}{V} \sum_{u \neq h, z \leq 0} \sum_{s_1=0}^{m_0} \max_{D \subseteq V(G)} \mathbf{P}(z \overset{s_1}{\leftrightarrow} u \text{ off } A \cup D) \mathbf{P}_{\text{off } A}(z \leftrightarrow h) \mathbf{P}_{\text{off } A}(u \overset{s}{\leftrightarrow} h).$$

We would like to sum the first term in the sum over s_1 and get a contribution of $\mathbf{P}(z \xrightarrow{m_0} u)$. We cannot do that however, because the maximizing set D may depend on s_1 so these are not necessarily disjoint events. Instead we bound for all $D \subseteq V(G)$

$$\mathbf{P}(z \xrightarrow{s_1} u \text{ off } A \cup D) \leq m(m-1)^{s_1} p_c^{s_1} \mathbf{p}^{s_1}(z, u) \leq (1+o(1)) \mathbf{p}^{s_1}(z, u)$$

where the first inequality is since $m(m-1)^{s_1} \mathbf{p}^{s_1}(z, u)$ bounds the number of simple paths of length s_1 connecting z to u and the second inequality is due to condition (2) of Theorem 1.3. Now, if one of the connections $z \leftrightarrow h$ or $u \leftrightarrow h$ is in fact a connection of length at least m_0 we use Lemma 3.13 to simplify the sum. For instance, if the connection is $z \xrightarrow{[m_0, \infty)} h$, then we bound the probability of this by $2V^{-1} \mathbb{E}|\mathcal{C}(0)|$ and the sum simplifies to

$$\frac{4G^*(r)F(s; A) \mathbb{E}|\mathcal{C}(0)|}{V^2} \sum_{u \neq h, z} \sum_{s_1=0}^{m_0} \mathbf{p}^{s_1}(z, u) \mathbf{P}(u \xrightarrow{s} h),$$

we then sum over h, u, z and s_1 and get a contribution of

$$\frac{4G^*(r)F(s; A) m_0 (\mathbb{E}|\mathcal{C}(0)|)^2}{V} = o(G^*(r)F(s; A)),$$

since $(\mathbb{E}|\mathcal{C}(0)|)^2 = O(V^{2/3})$ and $m_0 = o(\varepsilon^{-1}) = o(V^{1/3})$. Thus, it remains to bound

$$\frac{3G^*(r)F(s; A)}{V} \sum_{u \neq h, z} \sum_{s_1=0}^{m_0} \mathbf{p}^{s_1}(z, u) \mathbf{P}_{\text{off } A}(z \xrightarrow{m_0} h) \mathbf{P}_{\text{off } A}(u \xrightarrow{m_0} h).$$

We bound this by

$$\frac{CG^*(r)F(s; A)}{V} \sum_{u \neq h, z} \sum_{s_1=0, s_2=1, s_3=0}^{m_0} \mathbf{p}^{s_1}(z, u) \mathbf{p}^{s_2}(u, h) \mathbf{p}^{s_3}(h, z) = o(1) \cdot G^*(r)F(s; A),$$

where we used Claim 3.16 and condition (3) of Theorem 1.3. This concludes the proof of (4.1).

We now turn to prove the main result assuming (4.1). First, for any $r \leq 2m_0$ we have that the number of non-backtracking paths emanating from 0 is at most $m(m-1)^{r-1}$ and hence, for any A ,

$$G(r; A) \leq m(m-1)^{r-1} p_c^r = 1 + o(1),$$

by condition (2) of Theorem 1.3. It remains to consider the case $r \geq 2m_0$. Assume by contradiction that there exists some $r \geq 2m_0$ such that r is the maximizer in the definition $G^*(r)$ and that $G^*(r) \geq 2/c$ where c is the constant from (4.1). Fix such r and let $A = A(r)$ be the maximizing set as in (4.1). Now, putting $s = r$ in (4.1) gives

$$F(2r; A) \geq cG^*(r)F(r; A) \geq 2F(r; A).$$

Putting $s = 2r$ in (4.1) gives

$$F(3r; A) \geq cG^*(r)F(2r; A) \geq 4F(r; A),$$

and so, by induction, for any k ,

$$F(kr; A) \geq 2^{k-1}F(r; A).$$

We have reached a contradiction, since on the right hand side we have a quantity going to ∞ in k (note that A cannot contain 0, otherwise it will not be maximizing, so $F(r; A) \geq 1$) and on the left hand side our quantity is bounded by V . \square

We now wish to obtain the reverse inequality to Theorem 4.1, that is, a lower bound to $\mathbb{E}|\partial B(r)|$. Of course, this cannot hold for all r but it turns out to hold as long as $r \ll V^{1/3}$. This is the correct upper bound on r because the diameter of critical clusters is of order $V^{1/3}$ (see [48]).

Lemma 4.2 (Lower bound on critical expected ball). *Let G be any transitive finite graph and put $p = p_c$ where p_c is defined in (1.4). Then, there exists a constant $\xi > 0$ such that for all $r \leq \xi V^{1/3}$,*

$$\mathbb{E}|B(r)| \geq r/4.$$

Proof. For convenience write $c = 1/4$. Assume by contradiction that $\mathbb{E}|B(r)| \leq cr$. Given this assumption, we will prove by induction that for any integer $k \geq 0$,

$$\mathbb{E}|B([r(1+k/2), r(1+(k+1)/2)])| \leq 2^{k+1} c^{k+2} r. \quad (4.3)$$

Let us begin with the case $k = 0$. Since $\mathbb{E}|B(r)| \leq cr$ there exists $r' \in [r/2, r]$ such that $\mathbb{E}|\partial B(r')| \leq 2c$. Hence,

$$\begin{aligned} \mathbb{E}|B([r, 3r/2])| &= \sum_A \mathbf{P}(B(r') = A) \mathbb{E}[|B([r, 3r/2])| \mid B(r') = A] \\ &= \sum_A \mathbf{P}(B(r') = A) \mathbb{E}\left[\sum_{a \in \partial A} \mathbb{E}|B_a(3r/2 - r'; A)| \right] \\ &\leq cr \mathbb{E}|\partial B(r')| \leq 2c^2 r, \end{aligned}$$

where the inequality follows since $\mathbb{E}|B_a(3r/2 - r'; A)| \leq \mathbb{E}|B(r)| \leq cr$ for any A by monotonicity. Assume now that (4.3) holds for some k and we prove it for $k+1$. Since it holds for k , we have that there exists $r' \in [r(1+k/2), r(1+(k+1)/2)]$ such that $\mathbb{E}|\partial B(r')| \leq 2^{k+2} c^{k+2}$. By conditioning on $B(r') = A$ as before we get that

$$\mathbb{E}|B([r(1+(k+1)/2), r(1+(k+2)/2)])| \leq cr \cdot 2^{k+2} c^{k+2},$$

concluding the proof (4.3). Now, since $c < 1/2$ it is clear that the sum over k of (4.3) is at most Cr , contradicting the fact that $\mathbb{E}_{p_c}|\mathcal{C}(0)| = \lambda V^{1/3}$ by our definition of p_c in (1.4). Note that the constant ξ may depend on λ . \square

Lemma 4.3 (Lower bound on expected boundary size). *Let G be a transitive finite graph for which (1.5) holds and put $p = p_c$. Then there exists constants $c, \xi > 0$ such that for any $r \leq \xi V^{1/3}$,*

$$\mathbb{E}|\partial B(r)| \geq c.$$

Proof. By Lemma 4.2 and Theorem 2.1 we have that $\mathbb{E}|B([2r, Cr])| \geq r$ for some large fixed $C > 0$. Also,

$$\mathbb{E}|B(Cr)|^2 \leq \sum_{x,y} \mathbf{P}(0 \overset{Cr}{\leftrightarrow} x, 0 \overset{Cr}{\leftrightarrow} y) \leq \sum_{x,y,z} \mathbf{P}(0 \overset{Cr}{\leftrightarrow} z) \mathbf{P}(z \overset{Cr}{\leftrightarrow} x) \mathbf{P}(z \overset{Cr}{\leftrightarrow} y) \leq Cr^3,$$

by Theorem 2.1. By the inequality

$$\mathbf{P}(X > a) \geq (\mathbb{E}X - a)^2 / \mathbb{E}X^2 \quad (4.4)$$

valid for any non-negative random variable X and $a < \mathbb{E}X$, with $a = 0$,

$$\mathbf{P}(\partial B(2r) \neq \emptyset) \geq c/r,$$

for some $c > 0$. Furthermore, given $B(r)$, each vertex of $\partial B(r)$ has probability at most Cr^{-1} of reaching $\partial B(2r)$ by Theorem 2.1. Hence, for any $\zeta > 0$,

$$\mathbf{P}(\partial B(2r) \neq \emptyset \text{ and } |\partial B(r)| \leq \zeta r) \leq C^2 \zeta / r.$$

We now have

$$\begin{aligned} \mathbf{P}(|\partial B(r)| \geq \zeta r) &\geq \mathbf{P}(\partial B(2r) \neq \emptyset) - \mathbf{P}(\partial B(2r) \neq \emptyset \text{ and } |\partial B(r)| \leq \zeta r) \\ &\geq \frac{c}{r} - \frac{C^2 \zeta}{r}, \end{aligned}$$

and the lemma follows by choosing $\zeta > 0$ small enough. \square

4.2. In the supercritical regime. In this section, we extend the volume estimates to the supercritical regime. The following is an immediate corollary of Theorem 4.1:

Lemma 4.4 (Upper bound on supercritical volume). *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Then for any r and any $A \subset V$ we have*

$$\mathbb{E}|\partial B(t; A)| \leq C(1 + \varepsilon)^t, \quad \text{and} \quad \mathbb{E}|B(r; A)| \leq C\varepsilon^{-1}(1 + \varepsilon)^r.$$

Proof. The first assertion is immediate by Theorem 4.1 and Lemma 3.4. The second assertion follows by summing the first over $t \leq r$. \square

The corresponding lower bound is more complicated to obtain, and as before, can only hold up to some value of r . In conjunction with Lemma 4.4, it identifies $\mathbb{E}|B(r)| = \Theta(\varepsilon^{-1}(1 + \varepsilon)^r)$ for appropriate r 's.

Theorem 4.5 (Lower bound on supercritical volume). *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p = p_c(1 + \varepsilon)$. Then for any r satisfying*

$$\mathbb{E}|B(r)| \leq \frac{\varepsilon^2 V}{(\log \varepsilon^3 V)^4}, \tag{4.5}$$

the following bound holds:

$$\mathbb{E}|B(r)| \geq c\varepsilon^{-1}(1 + \varepsilon)^r.$$

Proof. First, we may assume that

$$r \leq \varepsilon^{-1} \log(\varepsilon^3 V), \tag{4.6}$$

since otherwise the assumption of the lemma cannot hold together with the conclusion. Recall now the simultaneous coupling (described at the end of Section 2.1) between percolation at $p_1 = p_c$ and $p_2 = p_c(1 + \varepsilon)$. Let

$$\mathcal{A}_\ell(x) = \{0 \stackrel{=}{\longleftrightarrow} x \text{ in } G_{p_2}\},$$

and given a simple path η of length ℓ between 0 and x , write

$$\mathcal{A}_\ell(x, \eta) = \{0 \stackrel{=}{\longleftrightarrow} x \text{ in } G_{p_2} \text{ and } \eta \text{ is the lexicographical first } p_2\text{-open path between } 0 \text{ and } x\},$$

so that $\mathcal{A}_\ell(x) = \bigcup_\eta \mathcal{A}_\ell(x, \eta)$. Write $\mathcal{B}_\ell(x, \eta)$ for the event that the edges of η are in fact p_1 -open (not just p_2). We have that

$$\mathcal{A}_\ell(x, \eta) \cap \mathcal{B}_\ell(x, \eta) \subseteq \{0 \stackrel{=}{\longleftrightarrow} x \text{ in } G_{p_1}\},$$

so,

$$\bigcup_{\ell \in [r - \varepsilon^{-1}, r], \eta} \mathcal{A}_\ell(x, \eta) \cap \mathcal{B}_\ell(x, \eta) \subseteq \{0 \stackrel{[r - \varepsilon^{-1}, r]}{\longleftrightarrow} x \text{ in } G_{p_1}\}. \tag{4.7}$$

We will show that

$$\sum_x \mathbf{P}\left(0 \stackrel{[r - \varepsilon^{-1}, r]}{\longleftrightarrow} x \text{ in } G_{p_1} \setminus \bigcup_{\ell \in [r - \varepsilon^{-1}, r], \eta} \mathcal{A}_\ell(x, \eta) \cap \mathcal{B}_\ell(x, \eta)\right) = o(\varepsilon^{-1}), \tag{4.8}$$

and first complete the proof subject to (4.8). Since $\{\mathcal{A}_\ell(x, \eta) \cap \mathcal{B}_\ell(x, \eta)\}_{\ell, \eta}$ are disjoint events, (4.7) and (4.8) show that

$$\sum_{x, \ell \in [r - \varepsilon^{-1}, r], \eta} \mathbf{P}(\mathcal{A}_\ell(x, \eta) \cap \mathcal{B}_\ell(x, \eta)) \geq \mathbb{E}_{p_1}|B([r - \varepsilon^{-1}, r])| - o(\varepsilon^{-1}) \geq c\varepsilon^{-1},$$

where the last inequality used Lemma 4.3 and the fact that $r \ll V^{1/3}$ by (4.6) and $\varepsilon \gg V^{-1/3}$. From this the required result follows since

$$\mathbf{P}(\mathcal{B}_\ell(x, \eta) \mid \mathcal{A}_\ell(x, \eta)) = (1 + \varepsilon)^{-\ell},$$

which implies that

$$\begin{aligned}
\mathbb{E}_{p_2}|B(r)| &\geq \sum_{x,\ell \in [r-\varepsilon^{-1},r],\eta} \mathbf{P}(\mathcal{A}_\ell(x,\eta)) \\
&= \sum_{x,\ell \in [r-\varepsilon^{-1},r],\eta} \mathbf{P}(\mathcal{A}_\ell(x,\eta))\mathbf{P}(\mathcal{B}_\ell(x,\eta) \mid \mathcal{A}_\ell(x,\eta))(1+\varepsilon)^\ell \\
&\geq (1+\varepsilon)^{r-\varepsilon^{-1}} \sum_{x,\ell \in [r-\varepsilon^{-1},r],\eta} \mathbf{P}(\mathcal{A}_\ell(x,\eta) \cap \mathcal{B}_\ell(x,\eta)) \\
&\geq (1+\varepsilon)^{r-\varepsilon^{-1}} c\varepsilon^{-1}.
\end{aligned} \tag{4.9}$$

Thus, our main effort is to show (4.8) under the restriction of (4.5) and (4.6). Fix x and assume that the event

$$\{0 \xrightarrow{[r-\varepsilon^{-1},r]} x \text{ in } G_{p_1}\} \setminus \bigcup_{\ell \in [r-\varepsilon^{-1},r],\eta} \mathcal{A}_\ell(x,\eta) \cap \mathcal{B}_\ell(x,\eta) \tag{4.10}$$

occurs. In words, this event means that either the shortest p_2 -open path is shorter than the shortest p_1 -path or that they have the same length but the lexicographically first shortest p_2 -path contains an edge having value in $[p_1, p_2]$. This implies that the p_2 -path *shortcuts* the p_1 -path. Formally, given vertices u, v and integers $\ell \in [r - \varepsilon^{-1}, r], k \in [0, \ell], t \in [2, \ell]$ with $k + t \leq \ell$ write $\mathcal{T}(u, v, x, \ell, k, t)$ for the event that there exists paths $\eta_1, \eta_2, \eta_3, \gamma$ in the graph such that

- (1) η_1 is a shortest p_1 -open path of length k connecting 0 to u ,
- (2) η_2 is a shortest p_1 -open path of length t connecting u to v ,
- (3) η_3 is a shortest p_1 -open path of length $\ell - t - k$ connecting v to x ,
- (4) $B_x(\ell - k - t) \cap B_0(k) = \emptyset$ in G_{p_1} ,
- (5) γ is p_2 -open path of length at most t connecting u to v and one of the edges of γ receives value in $[p_1, p_2]$, and
- (6) η_1, η_2, η_3 and γ are disjoint paths,

see Figure 2. The event (4.10) implies that $\mathcal{T}(u, v, x, \ell, k, t)$ occurs for some u, v, ℓ, k, t satisfying the conditions above. Our treatment of the case $t \geq m_0$ is easier than the case $t \leq m_0$ so let us perform this first. When $t \geq m_0$ we forget about condition (4) and the special edge with value $[p_1, p_2]$ in (5) and take a union over ℓ, k and $t \in [m_0, r]$ of the event $\mathcal{T}(u, v, x, \ell, k, t)$. This union implies the existence of vertices u, v such that the following events occur disjointly:

- (1) $0 \xrightarrow{r} u$ in G_{p_1} ,
- (2) $u \xrightarrow{P[m_0,r]} v$ in G_{p_1} ,
- (3) $v \xrightarrow{r} x$ in G_{p_1} ,
- (4) $u \xrightarrow{r} v$ in G_{p_2} .

Indeed, the witnesses to these (monotone) events are the paths $\eta_1, \eta_2, \eta_3, \gamma$. We now wish to use the BK inequality, however, as the astute reader may have already noticed, our witnesses are not stated in an i.i.d. product measure. Let us expand briefly on how we may still use the BK inequality. We may consider our simultaneous coupling measure to be an i.i.d. product measure by putting on each edge a countable infinite sequence of independent random bits receiving 0 with probability 1/2 and 1 otherwise such that this sequence encodes the uniform $[0, 1]$ random variable attached to each edge. In this setting, a witness for an edge being p -open is the sequence of bits attached to the edge and similarly for the edge being p -closed. Similarly, we define this way events of the form “ E_1 in G_{p_1} occurs disjointly from E_2 in G_{p_2} ”. With this definition of witnesses we may use the BK inequality here

FIGURE 2. The event $\mathcal{T}(u, v, x, \ell, k, t)$ — an excursion.

to bound the probability of the union above and sum over x (as in (4.8)). This gives an upper bound of

$$\sum_{u,v,x} \mathbf{P}_{p_1}(0 \stackrel{r}{\leftrightarrow} u) \mathbf{P}_{p_1}(u \stackrel{P[m_0,r]}{\leftrightarrow} v) \mathbf{P}_{p_1}(v \stackrel{r}{\leftrightarrow} x) \mathbf{P}_{p_2}(u \stackrel{r}{\leftrightarrow} v).$$

We sum over x and get a factor of r by Theorem 2.1. We bound $\mathbf{P}_{p_1}(u \stackrel{P[m_0,r]}{\leftrightarrow} v) \leq CrV^{-1}$ by Lemma 3.13 and Theorem 2.1. We then sum over v and get a factor of $\mathbb{E}_{p_2}|B(r)|$ and on u to get another factor of r . All together this gives an upper bound of

$$\frac{Cr^3 \mathbb{E}_{p_2}|B(r)|}{V} = O(\varepsilon^{-1} \log^{-1}(\varepsilon^3 V)) = o(\varepsilon^{-1}),$$

by (4.5).

We now treat the case in which $t \in [2, m_0]$. We claim that the event $\mathcal{T}(u, v, x, \ell, k, t)$ implies that there exist disjoint paths η_2, γ between u and v such that $|\eta_2| = t$ and $|\gamma| \leq t$ and the intersection of the following events occurs:

- (a) η_2 is p_1 -open,
- (b) γ is p_2 -open, and one of its edges receives value in $[p_1, p_2]$,
- (c) $0 \stackrel{=k}{\leftrightarrow} u$ off $\eta_2 \cup \gamma$ and $v \stackrel{=\ell-k-t}{\leftrightarrow} x$ off $\eta_2 \cup \gamma \cup B_0(k)$ in G_{p_1} .

Indeed, let $\eta_1, \eta_2, \eta_3, \gamma$ be the disjoint paths guaranteed to exist in the definition of $\mathcal{T}(u, v, x, \ell, k, t)$. The paths η_2 and γ show that both (a) and (b) indeed occur (note that we have relaxed the requirement that η_2 is a shortest p_1 -open path). Seeing that (c) occurs is slightly more subtle. First observe that for any two vertices z, y and integer $\ell \geq 0$

$$\{z \stackrel{=\ell}{\leftrightarrow} y \text{ off } A\} = \bigcup_{\beta: |\beta|=\ell, \beta \cap A = \emptyset} \left(\{\beta \text{ is open}\} \cap \bigcap_{\beta': |\beta'| < \ell, \beta' \cap A = \emptyset} \{\beta' \text{ has a closed edge}\} \right),$$

where β, β' are simple paths in G and we slightly abuse notation and write $\beta \cap A = \emptyset$ to denote that the edges of β are disjoint from the edges touching A . To see that (c) holds we note that the event $\mathcal{T}(u, v, x, \ell, k, t)$ implies that η_1 is of length k between 0 and u , disjoint from $\eta_2 \cup \gamma$, is p_1 -open and any shorter path between 0 and u has a p_1 -closed edge in it; in particular, $0 \stackrel{=k}{\leftrightarrow} u$ off $\eta_2 \cup \gamma$ occurs in G_{p_1} . Similarly, η_3 is of length $\ell - k - t$ between v and x , disjoint from $\eta_2 \cup \gamma \cup B_0(k)$, is p_1 -open and any shorter path between v and x has a p_1 -closed edge in it; in particular $v \stackrel{=\ell-k-t}{\leftrightarrow} x$ off $\eta_2 \cup \gamma \cup B_0(k)$ occurs in G_{p_1} .

Now, the events (a), (b), (c) are independent since they are measurable with respect to disjoint sets of edges (the edges of η_2, γ and all the rest). The probability of their intersection is hence

$$p_1^{|\eta_2|} p_2^{|\gamma|} [1 - (p_1/p_2)^{|\gamma|}] \mathbf{P}_{p_1}(0 \stackrel{=k}{\leftrightarrow} u \text{ off } \eta_2 \cup \gamma \text{ and } v \stackrel{=\ell-k-t}{\leftrightarrow} x \text{ off } \eta_2 \cup \gamma \cup B_0(k)),$$

where the factor $[1 - (p_1/p_2)^{|\gamma|}]$ is the probability that one edge of γ has value in $[p_1, p_2]$ conditioned on all edges being p_2 -open. We compute the probability on the right hand side as usual by conditioning on $B_0(k)$, this gives

$$p_1^{|\eta_2|} p_2^{|\gamma|} [1 - (p_1/p_2)^{|\gamma|}] \sum_{A: 0 \stackrel{=k}{\rightarrow} u} \mathbf{P}_{p_1}(B_0(k) = A) \mathbf{P}_{p_1}(v \stackrel{= \ell - k - t}{\leftarrow} x \text{ off } A \cup \eta_2 \cup \gamma).$$

We now start summing all this over $u, v, x, \ell, k, t, \eta_2, \gamma$. We start by summing over x the last probability, giving as a constant factor by Theorem 4.1. The sum over A gives a term of $\mathbf{P}_{p_1}(0 \stackrel{=k}{\rightarrow} u \text{ off } \eta_2 \cup \gamma)$ which we sum over $k \in [0, r]$ and bound this by $\mathbf{P}_{p_1}(0 \stackrel{r}{\leftarrow} u)$. Furthermore, the number of possible η_2 's is at most $m(m-1)^t \mathbf{p}^t(u, v)$ and if $|\gamma| = s \leq t$, then the number of such γ 's is at most $m(m-1)^{s-1} \mathbf{p}^s(u, v)$. We also bound $[1 - (p_1/p_2)^s] \leq C\epsilon$. All this gives that

$$\sum_{u, v, x, \ell, k, t \in [2, m_0]} \mathbf{P}(\mathcal{F}(u, v, x, \ell, k, t)) \leq C\epsilon \sum_{\substack{u, v, \ell \\ t \in [2, m_0], s \in [1, t]}} (m-1)^{s+t} p_1^t p_2^s \mathbf{sp}^t(u, v) \mathbf{p}^s(u, v) \mathbf{P}_{p_1}(0 \stackrel{r}{\leftarrow} u).$$

By condition (2) of Theorem 1.3 and the fact that $m_0 = o(\epsilon^{-1})$, we have that $(m-1)^{s+t} p_1^t p_2^s = 1 + o(\alpha_V)$, so we may bound this sum by

$$C\epsilon \sum_{u, \ell} \mathbf{P}_{p_1}(0 \stackrel{r}{\leftarrow} u) \sum_{v, t \in [2, m_0], s \in [1, t]} \mathbf{sp}^t(u, v) \mathbf{p}^s(u, v).$$

The sum over $\ell \in [r - \epsilon^{-1}, r]$ gives a factor of ϵ^{-1} , and since G is transitive, the second sum over v, t, s does not depend on u . Hence we may sum over u separately using Theorem 2.1 giving a bound of

$$Cr \sum_{v, t \in [2, m_0], s \in [1, t]} \mathbf{sp}^t(u, v) \mathbf{p}^s(u, v).$$

For each $s \geq 1$ and $s_1 \in \{1, \dots, s\}$, we can bound

$$\mathbf{p}^s(0, v) \leq \frac{m}{m-1} \sum_w \mathbf{p}^{s_1}(0, w) \mathbf{p}^{s-s_1}(w, v),$$

because the number of non-backtracking paths of length s from 0 to v is at most the sum over w the number of non-backtracking paths of length s_1 from 0 to w times the number of non-backtracking paths of length $s - s_1$ from w to v (the factor $m/(m-1)$ comes from properly normalizing these numbers). As a result,

$$\sum_{v, t \in [2, m_0], s \in [1, t]} \mathbf{sp}^t(0, v) \mathbf{p}^s(0, v) \leq \frac{m}{m-1} \sum_{v, w} \sum_{t \in [2, m_0], s_1 \in [1, t], s_2 \leq s_1} \mathbf{p}^t(0, v) \mathbf{p}^{s_1}(0, w) \mathbf{p}^{s_2}(w, v) \leq \frac{C\alpha_V}{\log V},$$

by condition (3) in Theorem 1.3 and the fact that $t + s_1 + s_2 \geq 3$. All together we get that

$$\sum_{u, v, x, \ell, k, t \in [2, m_0]} \mathbf{P}(\mathcal{F}(u, v, x, \ell, k, t)) \leq \frac{Cr\alpha_V}{\log V} = o(\epsilon^{-1}),$$

by our assumption (4.6) and since $\alpha_V = o(1)$. This finishes the proof of (4.8) and concludes the proof of the theorem. \square

The following are easy corollaries:

Corollary 4.6. *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p = p_c(1 + \epsilon)$. Then for any r satisfying*

$$r \leq \epsilon^{-1} [\log(\epsilon^3 V) - 4 \log \log(\epsilon^3 V)],$$

the following bound holds

$$\mathbb{E}|B(r)| = \Theta(\epsilon^{-1}(1 + \epsilon)^r).$$

In particular for r_0 defined in (2.8)

$$\mathbb{E}|B(r_0)| = \Theta(\sqrt{\alpha_V \varepsilon V}).$$

Proof. The upper bound follows from Lemma 4.4 and the lower bound from Theorem 4.5. \square

Lemma 4.7. *Let G be a graph satisfying the assumptions in Theorem 1.3 and consider percolation on it with $p \leq p_c(1 + \varepsilon)$. Let r be an integer satisfying the assumptions of Theorem 4.5. Then,*

$$\mathbb{E}|B(r)|^2 \leq C\varepsilon^{-1} (\mathbb{E}|B(r)|)^2.$$

Proof. If $0 \xleftrightarrow{r} x$ and $0 \xleftrightarrow{r} y$, then there exists a vertex z and an integer $t \leq r$ such that the event

$$\{0 \xleftrightarrow{=t} z\} \circ \{z \xleftrightarrow{r-t} x\} \circ \{z \xleftrightarrow{r-t} y\}$$

holds. Apply BK-Reimer and sum over x, y and then z to bound

$$\mathbb{E}|B(r)|^2 \leq \sum_{t=1}^r \mathbb{E}|\partial B(t)| \mathbb{E}|B(r-t)| \mathbb{E}|B(r-t)|.$$

We apply Lemma 4.4 and Theorem 4.1 to bound

$$\mathbb{E}|B(r)|^2 \leq C\varepsilon^{-3}(1 + \varepsilon)^{2r},$$

and Theorem 4.5 gives the required claim. \square

5. AN INTRINSIC-METRIC REGULARITY THEOREM

For an increasing event E and a vertex a , we say that a is *pivotal for E* for the event that E occurs but does not occur in the modified configuration in which we close all the edges touching a . We write $\text{Piv}(E)$ for the set of pivotal vertices for the event E . For vertices a, x , radii r_1, j_x and $A \subset V$, we define

$$G_{r_1, j_x}(a, x; A) = \mathbb{E}[|\{u: a \xleftrightarrow{P[2m_0, r_1]} u \text{ off } A \setminus \{a\} \text{ and } a \in \text{Piv}(\{x \xleftrightarrow{j_x+r_1} u\})\}| \mid B_x(j_x) = A].$$

Definition 5.1 (Regenerative and fit vertices). *(a) Given vertices x, a , radii $r_1, j_x \geq m_0$ and a real number $\beta > 0$, we say that a is (β, j_x, r_1) -regenerative if*

- (1) $x \xleftrightarrow{=j_x} a$, and
- (2) $G_{r_1, j_x}(a, x; B_x(j_x)) \geq (1 - \beta)\mathbb{E}|B(r_1)|$,

and note that this event is determined by the status of the edges touching $B_x(j_x)$. We say that a is (β, j_x, r_1) -nonregenerative if $x \xleftrightarrow{=j_x} a$ but it is not (β, j_x, r_1) -regenerative.

(b) Given an additional real number $\delta > 0$, we say that x is $(\delta, \beta, j_x, r_1)$ -fit if

- (1) $\partial B_x(j_x) \neq \emptyset$ holds and,
- (2) the number of (β, j_x, r_1) -nonregenerative vertices is at most $\delta\varepsilon^{-1}$.

It will also be convenient to combine our error terms. For this, we define

$$\omega_m = \alpha_V^{1/2} + \varepsilon m_0, \tag{5.1}$$

so that $\omega_m = o(1)$. Our goal in this section is to prove that if $\partial B_x(j_x) \neq \emptyset$, then x is fit with high probability. This is the *intrinsic metric* regularity theorem discussed in Section 2.5.

Theorem 5.1 (Intrinsic regularity). *Let G be a graph satisfying the assumptions of Theorem 1.3. Let $p = p_c(1 + \varepsilon)$, let $r = r_m = M/\varepsilon$ where $M = M_m$ is defined in (2.7) and $r_1 \in [\varepsilon^{-1}, r_0]$, where r_0 is defined in (2.8). For any $\delta, \beta \in (0, 1)$ there exist at least $(1 - O(\omega_m^{1/4}))r$ radii $j_x \in [r, 2r]$ such that*

$$\mathbf{P}(x \text{ is } (\delta, \beta, j_x, r_1)\text{-fit}) \geq (1 - O(\delta^{-1}\beta^{-2}e^{2M}\omega_m^{1/4}))\mathbf{P}(\partial B_x(j_x) \neq \emptyset).$$

We start by proving some preparatory lemmas:

Lemma 5.2. *Assume the setting of Theorem 5.1. Then,*

$$\sum_{j_x=r}^{2r} \sum_{a,u} \mathbf{P}(x \stackrel{=j_x}{\longleftrightarrow} a, a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } B_x(j_x) \setminus \{a\}) \geq (1 - O(\omega_m)) \mathbb{E}|B([r, 2r])| \mathbb{E}|B(r_1)|.$$

Proof. We condition on $B_x(j_x) = A$ for any admissible A (that is, A for which the event $x \stackrel{=j_x}{\longleftrightarrow} a$ occurs and $\mathbf{P}(B_x(j_x) = A) > 0$). Then,

$$\mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } B_x(j_x) \setminus \{a\} \mid B_x(j_x) = A) = \mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } A \setminus \{a\}),$$

and

$$\mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } A \setminus \{a\}) = \mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u) - \mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u \text{ only on } A \setminus \{a\}).$$

Summing over the first term gives

$$\begin{aligned} \sum_{a,u, j_x \in [r, 2r]} \mathbf{P}(x \stackrel{=j_x}{\longleftrightarrow} a) \mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u) &\geq \mathbb{E}|B([r, 2r])| (\mathbb{E}|B(r_1)| - \mathbb{E}|B(2m_0)|) \\ &= (1 - O(\omega_m)) \mathbb{E}|B(r_1)| \mathbb{E}|B([r, 2r])|, \end{aligned}$$

since $\mathbb{E}|B(2m_0)| \leq Cm_0$ by Corollary 3.5 and $\mathbb{E}|B(r_1)| \geq c\varepsilon^{-1}$ by Theorem 4.5 and since $r_1 \geq \varepsilon^{-1}$. It remains to bound the sum

$$\sum_{a,u, j_x \in [r, 2r]} \sum_A \mathbf{P}(B_x(j_x) = A) \mathbf{P}(a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u \text{ only on } A \setminus \{a\}).$$

As usual, if $a \stackrel{P[2m_0, r_1]}{\longleftrightarrow} u$ only on $A \setminus \{a\}$ occurs, then there exists $z \in A$ such that $\{a \stackrel{r_1}{\longleftrightarrow} z\} \circ \{z \stackrel{r_1}{\longleftrightarrow} u\}$. BK inequality now gives

$$\sum_{a,u, j_x \in [r, 2r]} \sum_A \mathbf{P}(B_x(j_x) = A) \sum_{z \in A \setminus \{a\}} \mathbf{P}(a \stackrel{r_1}{\longleftrightarrow} z) \mathbf{P}(z \stackrel{r_1}{\longleftrightarrow} u). \quad (5.2)$$

We sum over u and extract a factor of $\mathbb{E}|B(r_1)|$. We then change the order of summation, so the sum simplifies to

$$\mathbb{E}|B(r_1)| \sum_{a, z \neq a, j_x \in [r, 2r]} \mathbf{P}(x \stackrel{=j_x}{\longleftrightarrow} a, x \stackrel{j_x}{\longleftrightarrow} z) \mathbf{P}(a \stackrel{r_1}{\longleftrightarrow} z).$$

We sum over j_x (noting that the events $x \stackrel{=j_x}{\longleftrightarrow} a, x \stackrel{j_x}{\longleftrightarrow} z$ are disjoint as j_x varies) and bound this sum by

$$\mathbb{E}|B(r_1)| \sum_{a, z \neq a} \mathbf{P}(x \stackrel{2r}{\longleftrightarrow} a, x \stackrel{2r}{\longleftrightarrow} z) \mathbf{P}(a \stackrel{r_1}{\longleftrightarrow} z).$$

As usual, if $x \stackrel{2r}{\longleftrightarrow} a$ and $x \stackrel{2r}{\longleftrightarrow} z$, then there exists z' such that the event

$$\{x \stackrel{2r}{\longleftrightarrow} z'\} \circ \{z' \stackrel{2r}{\longleftrightarrow} z\} \circ \{z' \stackrel{2r}{\longleftrightarrow} a\}$$

occurs. By the BK inequality we bound the above sum by

$$\mathbb{E}|B(r_1)| \sum_{a, z', z \neq a} \mathbf{P}(x \stackrel{2r}{\longleftrightarrow} z') \mathbf{P}(z' \stackrel{2r}{\longleftrightarrow} z) \mathbf{P}(z' \stackrel{2r}{\longleftrightarrow} a) \mathbf{P}(a \stackrel{r_1}{\longleftrightarrow} z).$$

We may now sum over a and $z \neq a$ using Corollary 3.18 and then sum over z' to get that this is bounded by

$$C \mathbb{E}|B(r_1)| \mathbb{E}|B(2r)| \left[\omega_m + \frac{\mathbb{E}|B(r_1)| (\mathbb{E}|B(2r)|)^2}{V} \right].$$

This concludes our proof since the second term in the parenthesis is of order at most $\alpha_V^{1/2} e^{4M} (\varepsilon^3 V)^{-1/2} \leq \alpha_V^{1/2}$ by the upper bound on r_1 , our choice of r and M in (2.7) and Corollary 4.6. \square

FIGURE 3. a is not pivotal for the event $x \xleftrightarrow{j_x+r_1} u$.

Lemma 5.3. *Assume the setting of Theorem 5.1. There exists a $C > 0$, such that*

$$\sum_{j_x=r}^{2r} \sum_{a,u} \mathbf{P}(x \xleftrightarrow{j_x} a, a \xleftrightarrow{P[2m_0, r_1]} u \text{ off } B_x(j_x) \setminus \{a\}, a \in \text{Piv}(\{x \xleftrightarrow{j_x+r_1} u\})) \geq (1 - O(\omega_m)) |\mathbb{E}|B([r, 2r])| |\mathbb{E}|B(r_1)|.$$

Proof. Fix $j_x \in [r, 2r]$. We rely on Lemma 5.2, and bound the difference in the probabilities appearing in Lemma 5.2 and the one above. If the event

$$\{x \xleftrightarrow{j_x} a, a \xleftrightarrow{P[2m_0, r_1]} u \text{ off } B_x(j_x) \setminus \{a\}\} \quad (5.3)$$

occurs but $a \notin \text{Piv}(\{x \xleftrightarrow{j_x+r_1} u\})$, then there exist z_1, z_2 and $t \leq j_x$ and paths $\eta_1, \eta_2, \gamma_1, \gamma_2, \gamma_3$ such that

- (a) γ_1 is an open path of length at most r_1 connecting a to z_2 ,
- (b) γ_2 is an open path of length at most r_1 connecting z_2 to u ,
- (c) γ_3 is an open path of length at most $r_1 + j_x$ connecting z_1 to z_2 ,
- (d) η_1 is a shortest open path of length precisely t connecting x to z_1 ,
- (e) η_2 is a shortest open path of length precisely $j_x - t$ connecting z_1 to a ,
- (f) $\gamma_1, \gamma_2, \gamma_3, \eta_1, \eta_2$ are disjoint.

See Figure 3. Indeed, assume that a is not pivotal for $x \xleftrightarrow{j_x+r_1} u$ and (5.3) holds. Let η be the lexicographically first shortest open path of length j_x between x and a and γ a disjoint open path of length in $[2m_0, r_1]$ between a and u off $B_x(j_x) \setminus \{a\}$ which we are guaranteed to have since (5.3) holds. Since a is not pivotal we learn that there exists another open path β between x and u of length at most $j_x + r_1$ that does *not* visit a . Hence, β goes “around” a , or in formal words, there exists vertices z_1 and z_2 on β appearing on it in that order such that $z_1 \in \eta$ and $z_2 \in \gamma$ and the part of β between z_1 and z_2 is disjoint from $\eta \cup \gamma$. We take $t < j_x$ to be such that $\eta(t) = z_1$ and put $\eta_1 = \eta[0, t], \eta_2 = \eta[t, j_x]$. We take γ_3 to be the section of β between z_1 and z_2 and γ_1, γ_2 be the sections of γ from a to z_2 and from z_2 to u , respectively.

For all $j_x, t \in [r, 2r]$ these events (that is, the existence of z_1, z_2 and the disjoint paths) are disjoint since η_1 and η_2 are required to be shortest open paths. The union of these events over j_x, t implies that there exists z_1, z_2 such that

$$\{x \xleftrightarrow{2r} z_1\} \circ \{z_1 \xleftrightarrow{2r} a\} \circ \{a \xleftrightarrow{r_1} z_2\} \circ \{z_1 \xleftrightarrow{r_1+2r} z_2\} \circ \{z_2 \xleftrightarrow{r_1} u\},$$

since we can just take $\eta_1, \eta_2, \gamma_1, \gamma_2, \gamma_3$ as our disjoint witnesses. Using BK inequality we bound the required sum from above by

$$\sum_{\substack{a, u, z_1, z_2: \\ z_1 \neq z_2, z_1 \neq a, z_2 \neq a}} \mathbf{P}(x \overset{2r}{\longleftrightarrow} z_1) \mathbf{P}(z_1 \overset{2r}{\longleftrightarrow} a) \mathbf{P}(a \overset{r_1}{\longleftrightarrow} z_2) \mathbf{P}(z_1 \overset{r_1+2r}{\longleftrightarrow} z_2) \mathbf{P}(z_2 \overset{r_1}{\longleftrightarrow} u).$$

Summing first over u extracts a factor of $\mathbb{E}|B(r_1)|$, and we sum over a and z_2 using Corollary 3.18, and lastly sum over z_1 . This gives a bound of

$$C\mathbb{E}|B(r_1)|\mathbb{E}|B(2r)| \left[\omega_m + \frac{\mathbb{E}|B(r_1)|\mathbb{E}|B(r_1+2r)|\mathbb{E}|B(2r)|}{V} \right].$$

We apply Lemma 5.2 to conclude the proof since the second term in the parenthesis is of order at most $\alpha_V e^{4M} \leq \alpha_V^{1/2}$ by the upper bound on r_1 , our choice of r and M in (2.7) and Corollary 4.6. Also note that $\mathbb{E}|B([r, 2r])| \geq \mathbb{E}|B(2r)|/2$ by Corollary 4.6 and our choice of r and M . \square

Lemma 5.4. *Assume the setting of Theorem 5.1. For any vertices x, a ,*

$$\sum_{j_x=r}^{2r} \sum_u \mathbf{P}(x \overset{=j_x}{\longleftrightarrow} a, a \overset{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } B_x(j_x) \setminus \{a\}) \leq (1 + O(\omega_m)) V^{-1} \mathbb{E}|B(r_1)| \mathbb{E}|B([r, 2r])|.$$

Proof. The event $x \overset{=j_x}{\longleftrightarrow} a, a \overset{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } B_x(j_x) \setminus \{a\}$ implies that

$$\{x \overset{=j_x}{\longleftrightarrow} a\} \circ \{a \overset{r_1}{\longleftrightarrow} u\},$$

the second witness is the open edges of an open path of length in $[2m_0, r_1]$ off $B_x(j_x) \setminus \{a\}$ and the first witness is the lexicographically first shortest open path of length j_x between x and a together with all the closed edges of the graph. The BK-Reimer inequality gives that

$$\mathbf{P}(x \overset{=j_x}{\longleftrightarrow} a, a \overset{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } B_x(j_x) \setminus \{a\}) \leq \mathbf{P}(x \overset{=j_x}{\longleftrightarrow} a) \mathbf{P}(a \overset{r_1}{\longleftrightarrow} u).$$

We sum over u and $j_x \in [r, 2r]$ get that the sum is bounded by

$$\mathbb{E}|B(r_1)| \mathbf{P}(x \overset{[r, 2r]}{\longleftrightarrow} a).$$

Lemma 3.14 gives that

$$\mathbf{P}(x \overset{[r, 2r]}{\longleftrightarrow} a) \leq (1 + O(\omega_m)) V^{-1} \mathbb{E}|B([r - m_0, 2r - m_0])|.$$

We have that

$$\mathbb{E}|B([r - m_0, 2r - m_0])| \leq \mathbb{E}|B([r, 2r])| + \mathbb{E}|B([r - m_0, r])| \leq (1 + O(\varepsilon m_0)) \mathbb{E}|B([r, 2r])|$$

since $\mathbb{E}|B([r - m_0, r])| \leq C m_0 (1 + \varepsilon)^r$ by Theorem 4.1 and Corollary 3.5 and since $\mathbb{E}|B([r, 2r])| \geq c \varepsilon^{-1} (1 + \varepsilon)^{2r}$ by Corollary 4.6 (we use the assumption that $r \gg \varepsilon^{-1}$). Hence

$$\mathbf{P}(x \overset{[r, 2r]}{\longleftrightarrow} a) \leq (1 + O(\omega_m)) V^{-1} \mathbb{E}|B([r, 2r])|, \quad (5.4)$$

concluding our proof. \square

Proof of Theorem 5.1. By combining Lemmas 5.3 and 5.4 we deduce that for any x there exist at least $(1 - O(\omega_m^{1/2}))V$ vertices a such that

$$\sum_{j_x=r}^{2r} \sum_u \mathbf{P}(x \overset{=j_x}{\longleftrightarrow} a, a \overset{P[2m_0, r_1]}{\longleftrightarrow} u \text{ off } B_x(j_x) \setminus \{a\}, a \in \text{Piv}(\{x \overset{j_x+r_1}{\longleftrightarrow} u\})) = (1 + O(\omega_m^{1/2})) V^{-1} \mathbb{E}|B(r_1)| \mathbb{E}|B([r, 2r])|.$$

Write \tilde{G} for the variable

$$\tilde{G} = \sum_{j_x=r}^{2r} G_{j_x, r_1}(a, x; B_x(j_x)) \mathbf{1}_{\{x \overset{=j_x}{\longleftrightarrow} a\}}.$$

Note that \tilde{G} is a random variable that is measurable with respect to $B_x(2r)$ (that is, it is determined by the status of the edges touching $B_x(2r)$) and that it equals 0 unless $x \xleftrightarrow{[r,2r]} a$. Furthermore, only one of the summands can be nonzero because the events in the indicators are disjoint. Our previous approximate equality can be rewritten as

$$\mathbb{E}\tilde{G} = (1 + O(\omega_m^{1/2}))V^{-1}\mathbb{E}|B(r_1)|\mathbb{E}|B([r,2r])|.$$

Hence, for at least $(1 - O(\omega_m^{1/2}))V$ vertices a ,

$$\mathbb{E}[\tilde{G} \mid x \xleftrightarrow{[r,2r]} a] \geq (1 - O(\omega_m^{1/2}))\mathbb{E}|B(r_1)|, \quad (5.5)$$

by Lemma 3.14. This gives the conditional first moment estimate. The second moment calculation is somewhat easier. We have

$$\mathbb{E}\tilde{G}^2 = \sum_{j_x=r}^{2r} \sum_{u_1, u_2} \mathbb{E} \left[\mathbf{P}(a \xleftrightarrow{P[2m_0, r_1]} u_1 \text{ off } B_x(j_x) \setminus \{a\} \mid B_x(j_x)) \mathbf{P}(a \xleftrightarrow{P[2m_0, r_1]} u_2 \text{ off } B_x(j_x) \setminus \{a\} \mid B_x(j_x)) \mathbf{1}_{\{x \xleftrightarrow{[r,2r]} a\}} \right].$$

We bound, almost surely in $B_x(j_x)$ and for $i = 1, 2$,

$$\mathbf{P}(a \xleftrightarrow{P[2m_0, r_1]} u_i \text{ off } B_x(j_x) \setminus \{a\} \mid B_x(j_x)) \leq \mathbf{P}(a \xleftrightarrow{r_1} u_i),$$

and sum over u_1 and u_2 to get that

$$\mathbb{E}\tilde{G}^2 \mathbf{1}_{\{x \xleftrightarrow{[r,2r]} a\}} \leq [\mathbb{E}|B(r_1)|]^2 \mathbf{P}(x \xleftrightarrow{[r,2r]} a),$$

so that

$$\mathbb{E}[\tilde{G}^2 \mid x \xleftrightarrow{[r,2r]} a] \leq [\mathbb{E}|B(r_1)|]^2.$$

Combining this with (5.5), we obtain

$$\text{Var}(\tilde{G} \mid x \xleftrightarrow{[r,2r]} a) = O([\mathbb{E}|B(r_1)|]^2 \omega_m^{1/2}).$$

By Chebychev's inequality, for any $\beta > 0$,

$$\mathbf{P}(\tilde{G} \leq (1 - \beta)\mathbb{E}|B(r_1)| \mid x \xleftrightarrow{[r,2r]} a) = O(\beta^{-2} \omega_m^{1/2}).$$

Recall that this holds for at least $(1 - O(\omega_m^{1/2}))V$ vertices a . Call these vertices *valid*. We have

$$\sum_{a \text{ valid}} \mathbf{P}(x \xleftrightarrow{[r,2r]} a, \tilde{G} \leq (1 - \beta)\mathbb{E}|B(r_1)|) = O(\mathbb{E}|B([r,2r])| \beta^{-2} \omega_m^{1/2}),$$

by our previous estimate. Also, since there are at most $O(\omega_m^{1/2}V)$ invalid a 's, we apply (5.4) to bound the sum over all a by

$$\sum_a \mathbf{P}(x \xleftrightarrow{[r,2r]} a, \tilde{G} \leq (1 - \beta)\mathbb{E}|B(r_1)|) = O(\mathbb{E}|B([r,2r])| \beta^{-2} \omega_m^{1/2}).$$

Returning to our original notation, we rewrite this as

$$\sum_{j_x=r}^{2r} \sum_a \mathbf{P}(x \xleftrightarrow{[r,2r]} a, G_{j_x, r_1}(a, x; B_x(j_x)) \leq (1 - \beta)\mathbb{E}|B(r_1)|) = O(\mathbb{E}|B([r,2r])| \beta^{-2} \omega_m^{1/2}).$$

Hence, there are at least $(1 - O(\omega_m^{1/4}))r$ radii $j_x \in [r, 2r]$ such that

$$\begin{aligned} \sum_a \mathbf{P}(x \xleftrightarrow{[r,2r]} a, G_{j_x, r_1}(a, x; B_x(j_x)) \leq (1 - \beta)\mathbb{E}|B(r_1)|) &= O(\mathbb{E}|B([r,2r])| r^{-1} \beta^{-2} \omega_m^{1/4}) \\ &= O(e^{2M} \beta^{-2} \omega_m^{1/4}), \end{aligned}$$

where the last inequality is by Lemma 4.4. Given such j_x , write $X(j_x)$ for the random variable

$$X(j_x) = \left\{ a : x \xleftrightarrow{[r,2r]} a, G_{j_x, r_1}(a, x; B_x(j_x)) \leq (1 - \beta)\mathbb{E}|B(r_1)| \right\},$$

so that $\mathbb{E}X(j_x) \leq Ce^{2M}\beta^{-2}\omega_m^{1/4}$. The variable $X(j_x)$ equals the number of (β, j_x, r_1) -non-regenerative vertices. By Markov's inequality we get that for any $\delta > 0$

$$\mathbf{P}(X(j_x) \geq \delta\epsilon^{-1}) = O(\epsilon\delta^{-1}\beta^{-2}e^{2M}\omega_m^{1/4}),$$

and we conclude by Lemma 3.6 that at least $(1 - O(\omega_m^{1/4}))r$ radii $j_x \in [r, 2r]$ satisfy

$$\mathbf{P}(\partial B_x(j_x) \neq \emptyset \text{ and } X(j_x) \leq \delta\epsilon^{-1}) \geq (1 - O(\delta^{-1}\beta^{-2}e^{2M}\omega_m^{1/4}))\mathbf{P}(\partial B_x(j_x) \neq \emptyset),$$

as required. \square

6. LARGE CLUSTERS ARE CLOSE

In this section, we prove Theorem 2.4 which shows that many closed edges exist between most large clusters. This section involves all our notation from the previous sections and in particular the parameters $V, m, m_0, \epsilon_m, \alpha_V$. We define $\beta, k, \ell, \zeta, \delta$ as

$$\beta = (\log M)^{-2}, \quad k = \frac{M}{\log M}, \quad \ell = (\log M)^{1/4}, \quad \zeta = (\log M)^{-1/8}, \quad \delta = \zeta/2. \quad (6.1)$$

For notational convenience we also denote

$$\begin{aligned} \{a \xleftrightarrow{P[2m_0, r_0], x} u\} &= \{a \xleftrightarrow{P[2m_0, r_0]} u\} \cap \{a \in \text{Piv}(x \xleftrightarrow{j_x+r_0} u)\}, \\ \{b \xleftrightarrow{P[2m_0, r_0], y} u'\} &= \{b \xleftrightarrow{P[2m_0, r_0]} u'\} \cap \{b \in \text{Piv}(y \xleftrightarrow{j_y+r_0} u')\}. \end{aligned}$$

Let $S_{j_x, j_y, r_0}(x, y)$ be the random variable counting the number of edges (u, u') such that there exist vertices a, b with

- (1) $\mathcal{A}(x, y, j_x, j_y)$,
- (2) $x \xleftrightarrow{j_x} a$ and $y \xleftrightarrow{j_y} b$ and
- (3) $a \xleftrightarrow{P[2m_0, r_0], x} u$ and
- (4) $b \xleftrightarrow{P[2m_0, r_0], y} u'$ off $B_x(j_x + r_0)$.

Further define

$$\widehat{S}_{2r, 2r, r_0}(x, y) = \left| \{(u, u') : \{x \xleftrightarrow{2r+r_0} u\} \circ \{y \xleftrightarrow{2r+r_0} u'\}, |B_u(2r+r_0)| \cdot |B_{u'}(2r+r_0)| \geq e^{40M}\epsilon^{-2}(\mathbb{E}|B(r_0)|)^2\} \right|.$$

We will use the fact that for any $j_x, j_y \in \{r, \dots, 2r\}^2$

$$S_{2r+r_0}(x, y) \geq S_{j_x, j_y, r_0}(x, y) - \widehat{S}_{2r, 2r, r_0}(x, y), \quad (6.2)$$

where $S_{2r+r_0}(x, y)$ is the random variable defined above Theorem 2.4. Finally, write $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$ for the intersection of the events

- (1) $\mathcal{A}(x, y, j_x, j_y)$,
- (2) $|B_x(j_x)| \leq \epsilon^{-2}(1+\epsilon)^{3r}$ and $|B_y(j_y)| \leq \epsilon^{-2}(1+\epsilon)^{3r}$ and $|\partial B_x(j_x)| \leq \epsilon^{-1}(1+\epsilon)^{3r}$,
- (3) $|\partial B_x(j_x)| \geq e^{k/4}\epsilon^{-1}$ and $|\partial B_y(j_y)| \geq e^{k/4}\epsilon^{-1}$,
- (4) x is $(1, \beta, j_x, r_0)$ -fit and y is $(1, \beta, j_y, r_0)$ -fit,
- (5)

$$\mathbb{E} \left[S_{j_x, j_y, r_0}(x, y) \mathbf{1}_{\{|\partial B_x(j_x)| \geq 2r_0\}} \mid B_x(j_x), B_y(j_y) \right] \leq V^{-1} m \epsilon^{-2} (\mathbb{E}|B(r_0)|)^2 \alpha_V^{1/2}.$$

This event is measurable with respect to $B_x(j_x), B_y(j_y)$. The following three statements will prove Theorem 2.4:

Lemma 6.1. *Assume the setting of Theorem 2.4. Then,*

$$\mathbb{E} \left[\{x, y : \mathcal{A}(x, y, 2r, 2r) \text{ and } \widehat{S}_{2r, 2r, r_0}(x, y) \geq \beta^{1/2} V^{-1} m \epsilon^{-2} (\mathbb{E}|B(r_0)|)^2\} \right] = o(\epsilon^2 V^2).$$

Theorem 6.2. *Assume the setting of Theorem 2.4. Then there exists radii $j_1, \dots, j_\ell \in [r, 2r]$ such that for at least $(1 - o(1))V^2$ pairs x, y ,*

$$\mathbf{P}\left(\mathcal{A}(x, y, 2r, 2r) \text{ and } \bigcap_{j_x, j_y \in \{j_1, \dots, j_\ell\}^2} \mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)^c\right) = o(\varepsilon^2).$$

Theorem 6.3. *Assume the setting of Theorem 2.4 and let x, y be a pair of vertices. Then, for any radii $j_x, j_y \in \{r, \dots, 2r\}^2$,*

$$\mathbf{P}(S_{j_x, j_y, r_0}(x, y) \leq 2\beta^{1/2}V^{-1}m\varepsilon^{-2}(\mathbb{E}|B(r_0)|)^2 \text{ and } \mathcal{A}(x, y, j_x, j_y, r_0, \beta, k) = O(\beta^{1/2}\varepsilon^2)).$$

Proof of Theorem 2.4 subject to Lemma 6.1 and Theorems 6.2–6.3. Lemma 3.8 shows that

$$\frac{|\{x, y: \mathcal{A}(x, y, 2r, 2r)\}|}{4\varepsilon^2 V^2} \xrightarrow{\mathbb{P}} 1.$$

Thus, it suffices to prove that

$$\frac{|\{x, y: \mathcal{A}(x, y, 2r, 2r) \text{ and } x, y \text{ are not } (r, r_0)\text{-good}\}|}{\varepsilon^2 V^2} \xrightarrow{\mathbb{P}} 0.$$

Lemma 3.10 shows that

$$\frac{|\{x, y: \mathcal{A}(x, y, 2r, 2r) \text{ and } |\mathcal{C}(x)| \leq (\varepsilon^3 V)^{1/4} \varepsilon^{-2} \text{ or } |\mathcal{C}(y)| \leq (\varepsilon^3 V)^{1/4} \varepsilon^{-2}\}|}{\varepsilon^2 V^2} \xrightarrow{\mathbb{P}} 0.$$

We are left to handle requirement (3) in the definition of (r, r_0) -good. Let j_1, \dots, j_ℓ be the radii guaranteed to exist by Theorem 6.2 and let x, y be a pair of vertices for which the assertion of Theorem 6.2 holds. Theorem 6.2 asserts that the number of such pairs is $(1 - o(1))V^2$ so the sum of $\mathbf{P}(\mathcal{A}(x, y, 2r, 2r))$ over pairs not counted is $o(\varepsilon^2 V^2)$. Write $J(x), J(y)$ for the lexicographically first pair $(j_x, j_y) \in \{j_1, \dots, j_\ell\}^2$ for which the event $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$ occurs, or put $J(x) = J(y) = \infty$ if no such j_x, j_y exist. Then for at least $(1 - o(1))V^2$ pairs x, y

$$\mathbf{P}(\mathcal{A}(x, y, 2r, 2r), J(x) = \infty, J(y) = \infty) = o(\varepsilon^2).$$

Theorem 6.3 together with the union bound implies that for any such pair x, y

$$\sum_{j_x, j_y \in \{j_1, \dots, j_\ell\}^2} \mathbf{P}(S_{j_x, j_y, r_0}(x, y) \leq 2\beta^{1/2}V^{-1}m\varepsilon^{-2}(\mathbb{E}|B(r_0)|)^2, J(x) = j_x, J(y) = j_y) = O(\beta^{1/2}\ell^2\varepsilon^2),$$

which is $o(\varepsilon^2)$ by our choice of ℓ and β in (6.1). By these last two statements we deduce that

$$\mathbb{E}|\{x, y: \mathcal{A}(x, y, 2r, 2r) \text{ and } \forall j_x, j_y \ S_{j_x, j_y, r_0}(x, y) \leq 2\beta^{1/2}V^{-1}m\varepsilon^{-2}(\mathbb{E}|B(r_0)|)^2\}| = o(\varepsilon^2 V^2).$$

This together with (6.2) and Lemma 6.1 implies that

$$\mathbb{E}|\{x, y: \mathcal{A}(x, y, 2r, 2r) \text{ and } S_{2r+r_0}(x, y) \leq \beta^{1/2}V^{-1}m\varepsilon^{-2}(\mathbb{E}|B(r_0)|)^2\}| = o(\varepsilon^2 V^2),$$

concluding our proof since $\beta^{1/2} = (\log M)^{-1}$. \square

6.1. Proof of Lemma 6.1: Bounding the error $\widehat{S}_{2r, 2r, r_0}$. In this section, we prove Lemma 6.1. We begin by providing some useful estimates.

Lemma 6.4. *Assume the setting of Theorem 2.4 and let $p = p_c(1 + \varepsilon)$. There exists $C > 0$ such that for any positive integer n*

- (1) $\sum_{x, y, (u, u')} \mathbf{P}(\{u \xleftrightarrow{n} x\} \circ \{u' \xleftrightarrow{n} y\} \text{ and } u \xleftrightarrow{2n} u') \leq C[m\varepsilon^{-5}(1 + \varepsilon)^{4n} + \alpha_V V m\varepsilon^{-2}(1 + \varepsilon)^{2n}].$
- (2) $\sum_{x, y, (u, u')} \mathbf{P}(\{u \xleftrightarrow{n} x\} \circ \{u' \xleftrightarrow{n} y\} \text{ and } x \xleftrightarrow{2n} y) \leq C[m\varepsilon^{-5}(1 + \varepsilon)^{4n} + \alpha_V V m\varepsilon^{-2}(1 + \varepsilon)^{2n}].$

FIGURE 4. The edge (u, u') is counted in the first and second sum of Lemma 6.4.

Proof. We begin by showing (1). If $\{u \xleftrightarrow{n} x\} \circ \{u' \xleftrightarrow{n} y\}$ and $u \xleftrightarrow{2n} u'$, then there exists vertices z_1, z_2 and integers $t_1, t_2 \leq n$ such that the event

$$\{u \xleftrightarrow{=t_1} z_1, u' \xleftrightarrow{=t_2} z_2, d_{G_p}(u, u') \geq t_1 + t_2\} \circ \{z_1 \xleftrightarrow{2n-t_1-t_2} z_2\} \circ \{x \xleftrightarrow{n-t_1} z_1\} \circ \{y \xleftrightarrow{n-t_2} z_2\},$$

or the event

$$\{u \xleftrightarrow{=t_1} z_1, u' \xleftrightarrow{=t_2} z_2, d_{G_p}(u, u') \geq t_1 + t_2\} \circ \{z_1 \xleftrightarrow{2n-t_1-t_2} z_2\} \circ \{x \xleftrightarrow{n-t_1} z_2\} \circ \{y \xleftrightarrow{n-t_2} z_1\},$$

occur. See Figure 4 (a). Indeed, let η be the shortest open path of length at most $2n$ between u and u' and let $\gamma_{x,u}, \gamma_{y,u'}$ be two disjoint paths of length at most n connecting x to u and y to u' , respectively. We take z_1, z_2 to be the first vertices of $\gamma_{x,u}$ and $\gamma_{y,u'}$ which belongs to η . There are two possible orderings of z_1, z_2 on η , that is, (u, z_1, z_2, u') or (u, z_2, z_1, u') , which give the two possible events. Assume the ordering on η is (u, z_1, z_2, u') (the two orderings give rise to identical contributions to the sum in (1)), and put t_1, t_2 to be the distances on η between u and z_1 and between z_2 and u' , respectively and write η_1, η_2 to be the corresponding sections of η and η_3 is the section of η between z_1 and z_2 . The paths γ_1 and γ_2 are the sections of $\gamma_{x,u}$ and $\gamma_{y,u'}$ from x to z_1 and from y to z_2 , respectively. The witness for the first event is η_1, η_2 together with all the closed edges of G_p (the closed edges determine that η_1, η_2 are indeed shortest open paths, and that $d_{G_p}(u, u') \geq t_1 + t_2$), for the second, third and fourth events, the witnesses are just η_3, γ_1 and γ_2 , respectively.

We now apply the BK-Reimer inequality and bound the sum in (1) by

$$2 \sum_{x,y,z_1,z_2,(u,u'), t_1 \leq n, t_2 \leq n} \mathbf{P}(u \xleftrightarrow{=t_1} z_1, u' \xleftrightarrow{=t_2} z_2, d_{G_p}(u, u') \geq t_1 + t_2) \mathbf{P}(z_1 \xleftrightarrow{2n-t_1-t_2} z_2) \mathbf{P}(x \xleftrightarrow{n-t_1} z_1) \mathbf{P}(y \xleftrightarrow{n-t_2} z_2).$$

We first sum over x, y and get a factor of $C\varepsilon^{-2}(1+\varepsilon)^{2n-t_1-t_2}$ by Lemma 4.4. The event $u \xleftrightarrow{=t_1} z_1, u' \xleftrightarrow{=t_2} z_2, d_{G_p}(u, u') \geq t_1 + t_2$ implies that $u \xleftrightarrow{=t_1} z_1$ and $u' \xleftrightarrow{=t_2} z_2$ off $B_u(t_1)$ hence we may bound its probability by

$$\sum_{A: u \xleftrightarrow{=t_1} z_1} \mathbf{P}(B_u(t_1) = A) \mathbf{P}(u' \xleftrightarrow{=t_2} z_2 \text{ off } A),$$

and so we get an upper bound of

$$C\varepsilon^{-2} \sum_{z_1, z_2, (u, u'), t_1 \leq n, t_2 \leq n} (1+\varepsilon)^{2n-t_1-t_2} \mathbf{P}(u \xleftrightarrow{=t_1} z_1) \max_A \mathbf{P}(u' \xleftrightarrow{=t_2} z_2 \text{ off } A) \mathbf{P}(z_1 \xleftrightarrow{2n-t_1-t_2} z_2). \quad (6.3)$$

We bound this in two parts. If $t_2 \geq m_0$, then we use Lemma 3.15 together with Lemma 4.4 to bound, uniformly in A , $\mathbf{P}(u' \stackrel{=t_2}{\leftrightarrow} z_2 \text{ off } A) \leq CV^{-1}(1+\varepsilon)^{t_2}$. We then sum over z_2 and z_1 in that order using Lemma 4.4 and extract a Vm factor from summing over (u, u') . If $t_2 \leq m_0$ and $t_1 \geq m_0$, then we use Lemma 3.13 together with Lemma 4.4 to bound $\mathbf{P}(u \stackrel{=t_1}{\leftrightarrow} z_1) \leq CV^{-1}(1+\varepsilon)^{t_1}$. Further, we use condition (2) in Theorem 1.3 and $\varepsilon = o(m_0^{-1})$ to bound, uniformly in A , $\mathbf{P}(u' \stackrel{=t_2}{\leftrightarrow} z_2 \text{ off } A) \leq C\mathbf{p}^{t_2}(u', z_2)$. We then sum over z_1 and z_2 in that order using Lemma 4.4 and extract a Vm factor from summing over (u, u') . All this gives an upper bound of

$$Cm\varepsilon^{-3}(1+\varepsilon)^{4n} \sum_{t_1, t_2 \leq n} (1+\varepsilon)^{-t_1-t_2} \leq Cm\varepsilon^{-5}(1+\varepsilon)^{4n},$$

as required. We next sum (6.3) over $t_1, t_2 \leq m_0$. We first relax $(1+\varepsilon)^{2n-t_1-t_2} \leq (1+\varepsilon)^{2n}$ and $\mathbf{P}(z_1 \stackrel{2n-t_1-t_2}{\leftrightarrow} z_2) \leq \mathbf{P}(z_1 \stackrel{2n}{\leftrightarrow} z_2)$, and then sum over t_1, t_2 to get an upper bound of

$$C\varepsilon^{-2}(1+\varepsilon)^{2n} \sum_{z_1, z_2, (u, u')} \mathbf{P}(u \stackrel{m_0}{\leftrightarrow} z_1) \mathbf{P}(u' \stackrel{m_0}{\leftrightarrow} z_2) \mathbf{P}(z_1 \stackrel{2n}{\leftrightarrow} z_2).$$

We now sum over z_1, z_2 using Corollary 3.18 and Lemma 4.4. We get that this is bounded by

$$CVM\varepsilon^{-2}(1+\varepsilon)^{2n} \left[\frac{m_0^2 \varepsilon^{-1} (1+\varepsilon)^{2n}}{V} + \alpha_V \right] \leq C[m\varepsilon^{-5}(1+\varepsilon)^{4n} + \alpha_V VM\varepsilon^{-2}(1+\varepsilon)^{2n}],$$

since $m_0 \leq \varepsilon^{-1}$, as required.

To bound (2) we proceed in a very similar fashion. If $\{u \stackrel{n}{\leftrightarrow} x\} \circ \{u' \stackrel{n}{\leftrightarrow} y\}$ and $x \stackrel{2n}{\leftrightarrow} y$ then there exists vertices z_1, z_2 and $t_1, t_2 \leq n$ such that the event

$$\{x \stackrel{=t_1}{\leftrightarrow} z_1, y \stackrel{=t_2}{\leftrightarrow} z_2, d_{G_p}(x, y) \geq t_1 + t_2\} \circ \{z_1 \stackrel{2n-t_1-t_2}{\leftrightarrow} z_2\} \circ \{u \stackrel{n-t_1}{\leftrightarrow} z_1\} \circ \{u' \stackrel{n-t_2}{\leftrightarrow} z_2\},$$

or the event

$$\{x \stackrel{=t_1}{\leftrightarrow} z_2, y \stackrel{=t_2}{\leftrightarrow} z_1, d_{G_p}(x, y) \geq t_1 + t_2\} \circ \{z_1 \stackrel{2n-t_1-t_2}{\leftrightarrow} z_2\} \circ \{u \stackrel{n-t_1}{\leftrightarrow} z_1\} \circ \{u' \stackrel{n-t_2}{\leftrightarrow} z_2\},$$

occur, by the same reasoning as before, see Figure 4 (b). Let us handle the first case only (the second leads to an identical contribution). We appeal to the BK-Reimer inequality and as before we condition on $B_x(t_1)$ and bound

$$\mathbf{P}(x \stackrel{=t_1}{\leftrightarrow} z_1, y \stackrel{=t_2}{\leftrightarrow} z_2, d_{G_p}(x, y) \geq t_1 + t_2) \leq \sum_{A: x \stackrel{=t_1}{\leftrightarrow} z_1} \mathbf{P}(B_x(t_1) = A) \mathbf{P}(y \stackrel{=t_2}{\leftrightarrow} z_2 \text{ off } A).$$

We sum over y then x using Lemma 4.4 giving a bound of

$$C \sum_{z_1, z_2, (u, u'), t_1, t_2 \leq n} (1+\varepsilon)^{t_1+t_2} \mathbf{P}(u \stackrel{n-t_1}{\leftrightarrow} z_1) \mathbf{P}(z_1 \stackrel{2n-t_1-t_2}{\leftrightarrow} z_2) \mathbf{P}(u' \stackrel{n-t_2}{\leftrightarrow} z_2).$$

An appeal to Corollary 3.18 and Lemma 4.4 to sum over z_1, z_2 gives a bound of

$$CVM \sum_{t_1, t_2 \leq n} (1+\varepsilon)^{t_1+t_2} \left[\frac{\varepsilon^{-3}(1+\varepsilon)^{4n-2(t_1+t_2)}}{V} + \alpha_V \right] \leq C[m\varepsilon^{-5}(1+\varepsilon)^{4n} + \alpha_V VM\varepsilon^{-2}(1+\varepsilon)^{2n}],$$

where the last inequality is a direct calculation. \square

Proof of Lemma 6.1. For convenience put $n = 2r + r_0$. By Markov's inequality, the expectation we need to bound is at most

$$2\beta^{-1/2} Vm^{-1} \varepsilon^2 (\mathbb{E}|B(r_0)|)^{-2} \sum_{x, y, (u, u')} \mathbf{P}(\{x \stackrel{n}{\leftrightarrow} u\} \circ \{y \stackrel{n}{\leftrightarrow} u'\}, |B_u(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)|). \quad (6.4)$$

We split the sum into

$$S_1 = \sum_{x,y,(u,u')} \mathbf{P}(\{x \xrightarrow{n} u\} \circ \{y \xrightarrow{n} u'\}, |B_u(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)| \text{ and } B_u(n) \cap B_{u'}(n) = \emptyset),$$

and

$$S_2 = \sum_{x,y,(u,u')} \mathbf{P}(\{x \xrightarrow{n} u\} \circ \{y \xrightarrow{n} u'\}, u \xrightarrow{2n} u').$$

We bound S_1 using the BK inequality

$$S_1 \leq \sum_{x,y,(u,u')} \mathbf{P}(x \xrightarrow{n} u, |B_u(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)|) \mathbf{P}(y \xrightarrow{n} u').$$

Summing over y and x and then over (u, u') gives that this is at most

$$Vm \mathbb{E}|B(n)| \cdot \mathbb{E}|B(n)| \mathbf{1}_{\{|B(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)|\}}.$$

We use the Cauchy-Schwarz inequality to bound

$$\mathbb{E}|B(n)| \mathbf{1}_{\{|B(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)|\}} \leq [\mathbb{E}|B(n)|^2 \mathbf{P}(|B(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)|)]^{1/2}.$$

We bound this using Lemma 4.7 and the Markov inequality by

$$\mathbb{E}|B(n)| \mathbf{1}_{\{|B(n)| \geq e^{20M} \varepsilon^{-1} \mathbb{E}|B(r_0)|\}} \leq C e^{-10M} (\mathbb{E}|B(n)|)^{3/2} (\mathbb{E}|B(r_0)|)^{-1/2},$$

and conclude that

$$S_1 \leq C e^{-10M} Vm (\mathbb{E}|B(n)|)^{5/2} (\mathbb{E}|B(r_0)|)^{-1/2}.$$

We bound S_2 using part (1) of Lemma 6.4 by

$$S_2 \leq C [m \varepsilon^{-5} (1 + \varepsilon)^{4n} + \alpha_V Vm \varepsilon^{-2} (1 + \varepsilon)^{2n}].$$

We put these two back into (6.4) and get that we can bound this sum by

$$\frac{CV^2 \varepsilon^2 (\mathbb{E}|B(n)|)^{5/2}}{\beta^{1/2} e^{10M} (\mathbb{E}|B(r_0)|)^{5/2}} + \frac{CV \varepsilon^{-3} (1 + \varepsilon)^{4n}}{\beta^{1/2} (\mathbb{E}|B(r_0)|)^2} + \frac{Cm \alpha_V V^2 (1 + \varepsilon)^{2n}}{\beta^{1/2} m (\mathbb{E}|B(r_0)|)^2} = o(\varepsilon^2 V^2),$$

by our choice of r_0 in (2.8), $n = r_0 + 2r$, $r = M/\varepsilon$, $\beta = (\log M)^{-2}$ and using Corollary 4.6. \square

6.2. Proof of Theorem 6.2: Finding good radii. We proceed towards the proof of Theorem 6.2. Recall the choice of parameters in (6.1).

Lemma 6.5. *For any radius $r \geq \varepsilon^{-1}$ and any $\zeta > 0$,*

$$\mathbf{P}\left(|\partial B(r)| > 0 \text{ and } \exists j \in [\varepsilon^{-1}, r - \varepsilon^{-1}] \text{ with } |\partial B(j)| \leq \zeta \varepsilon^{-1}\right) \leq O(\zeta \varepsilon).$$

Proof. Assume that the event holds, and let J be the first radius j with $j \in [\varepsilon^{-1}, r - \varepsilon^{-1}]$ which has $|\partial B(j)| \leq \zeta \varepsilon^{-1}$. Conditioned on J and $B(J)$, for $|\partial B(r)| > 0$ to occur, one of the vertices on the boundary of $B(J)$ needs to reach level r . Since $r - j \geq \varepsilon^{-1}$, Corollary 3.5 and the union bound gives that this probability is at most $C\zeta$. This together with the fact that the probability of $|\partial B(j)| > 0$ is at most $C\varepsilon$, by Corollary 3.5, concludes the proof. \square

In the lemma below, we write $\mathbf{P}_A(\cdot) = \mathbf{P}(\cdot \text{ off } A \mid B_x(j_x) = A)$ and let \mathbb{E}_A be the corresponding expectation.

Lemma 6.6. *There exists $c > 0$ such that for any radius $j_x \in [r, 2r]$ the following statement holds. Let the set A be such that x is $(\delta, \beta, j_x, k\varepsilon^{-1})$ -fit and $|\partial B_x(j_x)| \geq \zeta \varepsilon^{-1}$ when $B_x(j_x) = A$. Then,*

$$\mathbf{P}_A(|\partial B_x(j_x + k\varepsilon^{-1}/2)| \geq \varepsilon^{-1} e^{k/4}) \geq c\zeta.$$

Proof. We perform a second moment argument on $|B_x([j_x + k\varepsilon^{-1}/2, j_x + k\varepsilon^{-1}]|$ rather than on the required random variable. Since x is $(\delta, \beta, j_x, k\varepsilon^{-1})$ -fit

$$\mathbb{E}_A |B_x([j_x, j_x + k\varepsilon^{-1}]|) \geq (|\partial A| - \delta\varepsilon^{-1})(1 - \beta)\mathbb{E}|B(k\varepsilon^{-1})|.$$

Furthermore,

$$\mathbb{E}_A |B_x([j_x, j_x + k\varepsilon^{-1}/2])| \leq |\partial A|\mathbb{E}|B(k\varepsilon^{-1}/2)|,$$

by monotonicity. Since $|\partial A| \geq 2\delta\varepsilon^{-1}$ by our choice of ζ and δ , and $\beta = o(1)$ (recall (6.1)), Corollary 4.6 now gives us a lower bound on the first moment

$$\mathbb{E}_A |B_x([j_x + k\varepsilon^{-1}/2, j_x + k\varepsilon^{-1}]|) \geq \frac{1}{4}|\partial A|\mathbb{E}|B(k\varepsilon^{-1})|,$$

To calculate the second moment, if u, v are counted in $|B([j_x, j_x + k\varepsilon^{-1}]|)$, then either there exists two vertices a_1, a_2 in ∂A such that

$$\{a_1 \xleftrightarrow{k\varepsilon^{-1}} u \text{ off } A\} \circ \{a_2 \xleftrightarrow{k\varepsilon^{-1}} v \text{ off } A\},$$

or there exists $a \in \partial A$, a vertex z and $t \leq k\varepsilon^{-1}$ such that

$$\{a \xleftrightarrow{=t} z \text{ off } A\} \circ \{z \xleftrightarrow{k\varepsilon^{-1}-t} u \text{ off } A\} \circ \{z \xleftrightarrow{k\varepsilon^{-1}-t} v \text{ off } A\}.$$

We apply the BK-Reimer inequality and sum over u, v . We get

$$\mathbb{E}_A |B_x([j_x, j_x + k\varepsilon^{-1}]|)^2 \leq |\partial A|^2 (\mathbb{E}|B(k\varepsilon^{-1})|)^2 + \sum_{a \in \partial A, z, t \leq k\varepsilon^{-1}} \mathbf{P}_A(a \xleftrightarrow{=t} z \text{ off } A) (\mathbb{E}|B(k\varepsilon^{-1} - t)|)^2.$$

We first sum over z using Lemma 4.4, then appeal again to Corollary 4.6 to get that

$$\mathbb{E}_A |B_x([j_x, j_x + k\varepsilon^{-1}]|)^2 \leq C(\mathbb{E}|B(k\varepsilon^{-1})|)^2 [|\partial A|^2 + |\partial A|\varepsilon^{-1}].$$

By (4.4),

$$\mathbf{P}_A(|B_x([j_x + k\varepsilon^{-1}/2, j_x + k\varepsilon^{-1}]|) \geq \frac{1}{8}|\partial A|\mathbb{E}|B(k\varepsilon^{-1})|) \geq \frac{c|\partial A|^2}{|\partial A|^2 + |\partial A|\varepsilon^{-1}} \geq c\zeta,$$

where the last inequality is since $|\partial A| \geq \zeta\varepsilon^{-1}$. By Theorem 4.5, we can write this as

$$\mathbf{P}_A(|B_x([j_x + k\varepsilon^{-1}/2, j_x + k\varepsilon^{-1}]|) \geq c\zeta\varepsilon^{-2}e^k) \geq c\zeta, \quad (6.5)$$

for some constant $c > 0$. Now, if $|B_x([j_x + k\varepsilon^{-1}/2, j_x + k\varepsilon^{-1}]|) \geq c\zeta\varepsilon^{-2}e^k$ and $|\partial B_x(j_x + k\varepsilon^{-1}/2)| \leq \varepsilon^{-1}e^{k/4}$ occurs, then

$$|\partial B_x(j_x + k\varepsilon^{-1}/2)| \leq \varepsilon^{-1}e^{k/4} \quad \text{and} \quad \sum_{v \in \partial B_x(j_x + k\varepsilon^{-1}/2)} |B_v(k\varepsilon^{-1}/2; A)| \geq c\zeta\varepsilon^{-2}e^k,$$

must both occur. By the Markov inequality and Lemma 4.4, the probability of this event is at most

$$\frac{\varepsilon^{-2}e^{3k/4}}{c\zeta\varepsilon^{-2}e^k} = O(\zeta^{-1}e^{-k/4}) = o(\zeta),$$

by our choice of ζ and k in (6.1). Putting this together with (6.5) yields the assertion of the lemma. \square

Lemma 6.7 (Finding good radii). *There exists radii k_1, \dots, k_ℓ in $[r, 2r]$ such that*

$$k_{i+1} - k_i \geq k\varepsilon^{-1},$$

for all $i = 1, \dots, \ell$ and

$$\begin{aligned} \mathbf{P}(x \text{ is } (\delta, \beta, k_i, k\varepsilon^{-1})\text{-fit}) &= (1 + O(\omega_m^{1/5}))\mathbf{P}(\partial B_x(k_i) \neq \emptyset), \\ \mathbf{P}(x \text{ is } (1, \beta, k_i, r_0)\text{-fit}) &= (1 + O(\omega_m^{1/5}))\mathbf{P}(\partial B_x(k_i) \neq \emptyset), \\ \mathbf{P}(x \text{ is } (\delta, \beta, k_i + k\varepsilon^{-1}/2, r_0)\text{-fit}) &= (1 + O(\omega_m^{1/5}))\mathbf{P}(\partial B_x(k_i + k\varepsilon^{-1}/2) \neq \emptyset). \end{aligned}$$

Proof. This is the only place where we use Theorem 5.1. Indeed, say a radius $j \in [r, 2r]$ is *good* if it satisfies the three assertions of the proposition with k_i replaced by j . Three appeals to Theorem 5.1 give that at least $(1 - o(1))r$ radii $j \in [r, 2r]$ are good by our choice of δ and β . Now, since $\ell k = o(M)$ and $r = M\varepsilon^{-1}$ it is immediate that there exist ℓ good radii which are $k\varepsilon^{-1}$ separated from each other. \square

Lemma 6.8. *For at least $(1 - o(1))V^2$ pairs x, y and for any $j_x, j_y \in [r, 2r]$,*

$$\mathbb{E}\left[S_{j_x, j_y, r_0} \mathbf{1}_{\{x \overset{2r_0+4r}{\longleftrightarrow} y\}}\right] \leq V^{-1} m(\mathbb{E}|B(r_0)|)^2 \alpha_V^{3/4}.$$

Proof. Part (2) of Lemma 6.4 with $n = r_0 + 2r$ and a straightforward calculation with Theorem 4.5 and our choice of parameters shows that

$$\sum_{x, y} \mathbb{E}\left[S_{j_x, j_y, r_0} \mathbf{1}_{\{x \overset{2r_0+j_x+j_y}{\longleftrightarrow} y\}}\right] \leq CVm(\mathbb{E}|B(r_0)|)^2 [\alpha_V e^{8M} + \alpha_V e^{4M}],$$

which gives the result since $C\alpha_V e^{8M} \leq \alpha_V^{3/4}$ by our choice of M in (2.7). \square

Proof of Theorem 6.2. Recall the requirements (1)-(5) in the definition of $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$. We apply Lemma 6.7 and let k_1, \dots, k_ℓ be the corresponding radii. We prove the theorem with radii $\{j_1, \dots, j_\ell\}$ defined by

$$j_i = k_i + k\varepsilon^{-1}/2,$$

for $i = 1, \dots, \ell$ and assume x, y are such that the assertion of Lemma 6.8 holds. We will prove that for these pairs x, y

$$\mathbf{P}\left(\mathcal{A}(x, y, 2r, 2r) \text{ and } \bigcap_{j_x, j_y \in \{j_1, \dots, j_\ell\}} \{(q) \text{ does not hold for } j_x, j_y\}\right) = o(\varepsilon^2), \quad (6.6)$$

for $q \in \{1, 2, 3, 4, 5\}$. We do this in the order (1), (2), (4), (5) and (3). Since $\mathcal{A}(x, y, 2r, 2r) \subseteq \mathcal{A}(x, y, j_x, j_y)$ when $j_x, j_y \leq 2r$, (6.6) holds trivially for $q = 1$ and all $x, y, j_x, j_y \leq 2r$.

For any $j_x \in \{j_1, \dots, j_\ell\}$,

$$\mathbf{P}(\mathcal{A}(x, y, j_x, j_y) \text{ and } |B_x(j_x)| \geq \varepsilon^{-2}(1 + \varepsilon)^{3r}) \leq C\varepsilon^2(1 + \varepsilon)^{-r} = O(e^{-M}\varepsilon^2),$$

by the Markov inequality, Lemma 4.4, the BK-Reimer inequality and Corollary 3.5. This implies that

$$\mathbf{P}(\mathcal{A}(x, y, 2r, 2r) \text{ and } \exists j_x \in \{j_1, \dots, j_\ell\} \text{ such that } |B_x(j_x)| \geq \varepsilon^{-2}(1 + \varepsilon)^{3r}) = o(\varepsilon^2),$$

since $\ell = o(e^M)$. Similarly,

$$\mathbf{P}(\mathcal{A}(x, y, j_x, j_y) \text{ and } |\partial B_x(j_x)| \geq \varepsilon^{-1}(1 + \varepsilon)^{3r}) \leq C\varepsilon^2(1 + \varepsilon)^{-r} = O(e^{-M}\varepsilon^2),$$

leading to the same bound. This proves (6.6) for $q = 2$.

Next, we wish to show that for any $j_x \in \{j_1, \dots, j_\ell\}$,

$$\mathbf{P}(\mathcal{A}(x, y, j_x, j_y) \text{ and } x \text{ is not } (1, \beta, j_x, r_0)\text{-fit}) = O(\varepsilon^2 \omega_m^{1/5}). \quad (6.7)$$

It is tempting to use the BK-Reimer inequality here, however, we cannot claim that the event in (6.7) implies that $\partial B_y(j_y) \neq \emptyset$ occurs disjointly from the event x is not $(1, \beta, j_x, r_0)$ -fit, since they are both non-monotone events and the corresponding witnesses may share closed edges. Instead, we condition $B_x(j_x) = A$ and get that

$$\mathbf{P}(\mathcal{A}(x, y, j_x, j_y) \text{ and } x \text{ is not } (1, \beta, j_x, r_0)\text{-fit}) = \sum_{A: x \text{ is not } (1, \beta, j_x, r_0)\text{-fit}} \mathbf{P}(B_x(j_x) = A) \mathbf{P}(\partial B_y(j_y) \neq \emptyset \text{ off } A),$$

since $(1, \beta, j_x, r_0)$ -fit is determined by the status of the edges touching $B_x(j_x)$. We use Corollary 3.5 to bound $\mathbf{P}(\partial B_y(j_y) \neq \emptyset \text{ off } A) = O(\varepsilon)$ and

$$\begin{aligned} \mathbf{P}(\partial B_x(j_x) \neq \emptyset \text{ and } x \text{ is not } (1, \beta, j_x, r_0)\text{-fit}) &= \mathbf{P}(\partial B_x(j_x) \neq \emptyset) - \mathbf{P}(\partial B_x(j_x) \neq \emptyset \text{ and } x \text{ is } (1, \beta, j_x, r_0)\text{-fit}) \\ &\leq \mathbf{P}(\partial B_x(j_x) \neq \emptyset) O(\omega_m^{1/5}), \end{aligned}$$

by our choice of radii in Lemma 6.7, so Corollary 3.5 gives (6.7). Therefore,

$$\mathbf{P}(\mathcal{A}(x, y, 2r, 2r) \text{ and } \exists j_x \in \{j_1, \dots, j_\ell\} \text{ such that } x \text{ is not } (1, \beta, j_x, r_0)\text{-fit}) = O(\ell \varepsilon^2 \omega_m^{1/5}) = o(\varepsilon^2),$$

by our choice of ℓ in (6.1), of M in (2.7), and of ω_m in (5.1). This proves (6.6) for $q = 4$.

Similarly, by Lemma 6.8 and Markov's inequality, for any j_x, j_y ,

$$\mathbf{P}(\mathcal{A}(x, y, j_x, j_y) \text{ and (5) does not hold}) \leq C\varepsilon^2 \alpha_V^{1/4}.$$

The union bound implies that

$$\mathbf{P}(\mathcal{A}(x, y, 2r, 2r) \text{ and } \exists j_x, j_y \in \{j_1, \dots, j_\ell\} \text{ (5) does not hold}) = O(\ell^2 \alpha_V^{1/4} \varepsilon^2) = o(\varepsilon^2),$$

by our choice of ℓ . Therefore, (6.6) holds for $q = 5$.

Thus, it remains to prove (6.6) for $q = 3$. This is the difficult requirement in which we only prove that one of the radii in $\{j_1, \dots, j_\ell\}$ satisfies it (in fact, all radii satisfy it, but that is harder to prove, and we refrain from doing so). In the same way as in the proof of (6.6) for $q = 4$, using Corollary 3.5, it is enough to show that

$$\mathbf{P}(\partial B_x(2r) \neq \emptyset \text{ and } |\partial B_x(j_x)| \leq e^{k/4} \varepsilon^{-1} \quad \forall j_x \in \{j_1, \dots, j_\ell\}) = o(\varepsilon). \quad (6.8)$$

For $i \in \{1, \dots, \ell\}$, we write \mathcal{A}_i for the event that x is $(\delta, \beta, k_i, k\varepsilon^{-1})$ -fit and \mathcal{B}_i for the event that $|\partial B_x(j_i)| \leq \varepsilon^{-1} e^{k/4}$ and \mathcal{D}_i for the event

$$\mathcal{D}_i = \{|\partial B_x(k_t)| \geq \zeta \varepsilon^{-1} \quad \forall t \in \{1, \dots, i\}\},$$

so that

$$\mathbf{P}(\partial B_x(2r) \neq \emptyset \text{ and } |\partial B_x(j_x)| \leq \varepsilon^{-1} e^{k/4}) \leq \mathbf{P}(\mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_\ell) + \mathbf{P}(\{\partial B_x(2r) \neq \emptyset\} \cap \mathcal{D}_\ell^c).$$

Then we can split

$$\mathbf{P}(\mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_\ell) \leq \mathbf{P}(\mathcal{D}_\ell \cap \mathcal{A}_\ell^c) + \mathbf{P}(\mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_\ell \cap \mathcal{A}_\ell).$$

By our choice of k_i in Lemma 6.7 and Corollary 3.5 we have that $\mathbf{P}(\mathcal{D}_\ell \cap \mathcal{A}_\ell^c) \leq \varepsilon \omega_m^{1/5}$, so that

$$\mathbf{P}(\mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_\ell) \leq \varepsilon \omega_m^{1/5} + \mathbf{P}(\mathcal{B}_\ell \mid \mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_{\ell-1} \cap \mathcal{A}_\ell) \mathbf{P}(\mathcal{D}_{\ell-1} \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_{\ell-1}).$$

Thus, by Lemma 6.6,

$$\mathbf{P}(\mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_\ell) \leq \varepsilon \omega_m^{1/5} + (1 - c\zeta) \mathbf{P}(\mathcal{D}_{\ell-1} \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_{\ell-1}),$$

By iterating this we obtain

$$\mathbf{P}(\mathcal{D}_\ell \cap \mathcal{B}_1 \cap \dots \cap \mathcal{B}_\ell) \leq \varepsilon \ell \omega_m^{1/5} + C\varepsilon(1 - c\zeta)^\ell = o(\varepsilon),$$

since $\ell \omega_m^{1/5} = o(1)$ and $\zeta^{-1} = o(\ell)$ (recall (6.1)), and $\mathbf{P}(\mathcal{D}_1) \leq C\varepsilon$ by Corollary 3.5. Lastly, Lemma 6.5 shows that

$$\mathbf{P}(\{\partial B_x(2r) \neq \emptyset\} \cap \mathcal{D}_\ell^c) = o(\varepsilon),$$

showing (6.8) and thus concluding the proof of (6.6) for $q = 3$ and the proof of Theorem 6.2. \square

6.3. Proof of Theorem 6.3: Conditional second moment. We now set the stage for the proof of Theorem 6.3. We perform this by a conditional second moment argument on $S_{j_x, j_y, r_0}(x, y)$. We will be conditioning on $B_x(j_x) = A$ and $B_y(j_y) = B$ where A and B are such that the event $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$ holds. We abuse notation, as before, and treat A, B as sets of vertices but our conditioning is on the status of all edges touching $B_x(j_x - 1)$ and $B_y(j_y - 1)$. Thus, while A and B are disjoint sets of vertices, they may be sharing closed edges. With this in mind, we generalize the notation just before Lemma 6.6, and write \mathbf{P}_A , \mathbf{P}_B and $\mathbf{P}_{A,B}$ for the measures

$$\begin{aligned} \mathbf{P}_A(\cdot) &= \mathbf{P}(\cdot \text{ off } A \mid B_x(j_x) = A), \\ \mathbf{P}_B(\cdot) &= \mathbf{P}(\cdot \text{ off } B \mid B_y(j_y) = B), \\ \mathbf{P}_{A,B}(\cdot) &= \mathbf{P}(\cdot \text{ off } A \cup B \mid B_x(j_x) = A, B_y(j_y) = B). \end{aligned}$$

We start by proving five preparatory lemmas.

Lemma 6.9. *Assume that A, B are such that x, y are $(1, \beta, j_x, r_0)$ -fit and $(1, \beta, j_y, r_0)$ -fit, respectively. Then,*

$$\sum_{a, b \in \partial A \times \partial B} \sum_{(u, u')} \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u') \geq (1 - 8\beta^{1/2})V^{-1}(\mathbb{E}|B(r_0)|)^2 m(|\partial A| - \varepsilon^{-1})(|\partial B| - \varepsilon^{-1}).$$

Proof. Let $a \in \partial A$ be a (β, j_x, r_0) -regenerative vertex. Then, by definition,

$$\sum_u \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \geq (1 - \beta)\mathbb{E}|B(r_0)|.$$

Denote by U the set of vertices

$$U = \{u: \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \leq (1 - \beta^{1/2})V^{-1}\mathbb{E}|B(r_0)|\},$$

and recall that Lemma 3.15 guarantees that

$$\mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \leq \frac{(1 + o(\beta))\mathbb{E}|B(r_0)|}{V},$$

by our choice of β in (6.1), so that

$$(1 - \beta)\mathbb{E}|B(r_0)| \leq \sum_u \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \leq |U|(1 - \beta^{1/2})V^{-1}\mathbb{E}|B(r_0)| + (V - |U|)(1 + o(\beta))V^{-1}\mathbb{E}|B(r_0)|,$$

and we deduce that $|U| \leq 2\beta^{1/2}V$. In other words, for at least $(1 - 2\beta^{1/2})V$ vertices u ,

$$\mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \geq \frac{(1 - \beta^{1/2})\mathbb{E}|B(r_0)|}{V}.$$

Similarly, for any $b \in \partial B$ which is (β, j_y, r_0) -regenerative, there exist at least $(1 - 2\beta^{1/2})V$ vertices u such that

$$\mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u) \geq \frac{(1 - \beta^{1/2})\mathbb{E}|B(r_0)|}{V}.$$

Thus, for such a and b , at least $(1 - 4\beta^{1/2})V$ vertices u satisfy both inequalities. Write D for this set of vertices so that $|D^c| \leq 4\beta^{1/2}V$. Since the degree of each vertex is m , the number of edges having at least one side in D^c is at most $4\beta^{1/2}Vm$. Thus, at least $(1 - 8\beta^{1/2})Vm$ directed edges (u, u') are such that u and u' both satisfy the above inequalities. Hence

$$\sum_{(u, u')} \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u') \geq \frac{(1 - 8\beta^{1/2})(\mathbb{E}|B(r_0)|)^2 m}{V}.$$

Since x is $(1, \beta, j_x, r_0)$ -fit and y is $(1, \beta, j_y, r_0)$ -fit the number of such pairs a, b is at least

$$(|\partial A| - \varepsilon^{-1})(|\partial B| - \varepsilon^{-1}),$$

and the lemma follows. \square

Lemma 6.10. *The following bounds hold:*

$$\sum_{\substack{(a, b) \in \partial A \times \partial B \\ (u, u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A, B}(a \xleftrightarrow{P[2m_0, r_0]} u, a \xleftrightarrow{r_0} z_1) \mathbf{P}_B(b \xleftrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{r_0 - t_1} u') \leq \alpha_V^{1/2} |\partial A| |\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2,$$

and

$$\sum_{\substack{(a, b) \in \partial A \times \partial B \\ (u, u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A, B}(a \xleftrightarrow{P[2m_0, r_0]} u, a \xleftrightarrow{r_0} z_1) \mathbf{P}_B(b \xleftrightarrow{r_0 - t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{=t_1} u') \leq \alpha_V^{1/2} |\partial A| |\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2.$$

Proof. The proof of the second assertion is identical to the first, so we only prove the first. If $a \xleftrightarrow{P[2m_0, r_0]} u$ and $a \xleftrightarrow{r_0} z_1$, then there exists z_2 and $t_2 \in [m_0, r_0]$ such that

$$\{a \xleftrightarrow{=t_2} z_2\} \circ \{z_2 \xleftrightarrow{r_0-t_2} u\} \circ \{z_2 \xleftrightarrow{r_0-t_2} z_1\}$$

or there exists z_2 such that

$$\{a \xleftrightarrow{m_0} z_2\} \circ \{z_2 \xleftrightarrow{P[m_0, r_0]} u\} \circ \{z_2 \xleftrightarrow{P[m_0, r_0]} z_1\}$$

or there exists z_2 such that

$$\{a \xleftrightarrow{P[m_0, r_0]} z_2\} \circ \{z_2 \xleftrightarrow{m_0} u\} \circ \{z_2 \xleftrightarrow{P[m_0, r_0]} z_1\}.$$

To see this, let η be the lexicographically first shortest open path between a and z_1 so that $|\eta| \leq r_0$ and let γ be an open path between a and u such that $|\gamma| \in [2m_0, r_0]$. Let z_2 be the last vertex (according to the ordering induced by γ) on γ belonging to η (that is, the part of γ after z_2 is disjoint from η and the part of η after z_2 is disjoint from γ). Let t_2 be the distance between a and z_2 along η . If $t_2 \geq m_0$, then the first event occurs: the first witness is the first t_2 open edges of η together with all the closed edges in the graph, the second witness is the set of open edges of γ between z_2 to u (note that there are no more than $r_0 - t_2$ edges since the part of γ between a to z_2 is of length at least t_2) and the third witness is the set of open edges of η between z_2 and u . If $t_2 \leq m_0$ occurs and the part of γ between z_2 and u is longer than m_0 , then the second event occurs by similar reasoning. Finally, if $t_2 \leq m_0$ occurs and the part of γ between z_2 and u is of length at most m_0 , then the part of γ between a and z_2 is longer than m_0 and the third event occurs.

This leads to three different terms, we use the BK-Reimer inequality and get that the required sum is at most $S^{(a)} + S^{(b)} + S^{(c)}$, where

$$S^{(a)} = \sum_{\substack{(a,b) \in \partial A \times \partial B, (u, u'), \\ z_1, z_2, t_1, t_2 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xleftrightarrow{=t_2} z_2) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{r_0-t_2} u) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{r_0-t_2} z_1) \mathbf{P}_B(b \xleftrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{r_0-t_1} u'),$$

and

$$S^{(b)} = \sum_{\substack{(a,b) \in \partial A \times \partial B, (u, u'), \\ z_1, z_2, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xleftrightarrow{m_0} z_2) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{P[m_0, r_0]} u) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{P[m_0, r_0]} z_1) \mathbf{P}_B(b \xleftrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{r_0-t_1} u'),$$

and

$$S^{(c)} = \sum_{\substack{(a,b) \in \partial A \times \partial B, (u, u'), \\ z_1, z_2, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xleftrightarrow{P[m_0, r_0]} z_2) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{m_0} u) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{P[m_0, r_0]} z_1) \mathbf{P}_B(b \xleftrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{r_0-t_1} u').$$

We use Lemma 3.15 together with Lemma 4.4 to bound the factors $\mathbf{P}_{A,B}(a \xleftrightarrow{=t_2} z_2)$ and $\mathbf{P}_B(b \xleftrightarrow{=t_1} z_1)$ in $S^{(a)}$ by $CV^{-1}(1+\varepsilon)^{t_2}$ and $CV^{-1}(1+\varepsilon)^{t_1}$, respectively. This gives

$$S^{(a)} \leq CV^{-2} \sum_{\substack{(a,b) \in \partial A \times \partial B, (u, u'), \\ t_1, t_2 \in [m_0, r_0]}} (1+\varepsilon)^{t_1+t_2} \sum_{z_1, z_2} \mathbf{P}_{A,B}(z_2 \xleftrightarrow{r_0-t_2} u) \mathbf{P}_{A,B}(z_2 \xleftrightarrow{r_0-t_2} z_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{r_0-t_1} u').$$

We sum over z_1, z_2 using Corollary 3.18 together with Lemma 4.4 to get that

$$\begin{aligned} S^{(a)} &\leq CV^{-2} \sum_{\substack{(a,b) \in \partial A \times \partial B, (u, u'), \\ t_1, t_2 \in [m_0, r_0]}} (1+\varepsilon)^{t_1+t_2} \left[\alpha_V + \frac{\varepsilon^{-3}(1+\varepsilon)^{3r_0-t_1-2t_2}}{V} \right] \\ &\leq C\alpha_V m |\partial A| |\partial B| V^{-1} \varepsilon^{-2} (1+\varepsilon)^{2r_0} + C |\partial A| |\partial B| V^{-2} m \varepsilon^{-4} (1+\varepsilon)^{3r_0} r_0, \end{aligned}$$

where the last inequality is an immediate calculation. By Theorem 4.5 the first term is at most

$$C\alpha_V |\partial A| |\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2,$$

and by our choice of r_0 in (2.8), the second term is at most

$$\frac{\alpha_V^{1/2} \log(\varepsilon^3 V)}{\sqrt{\varepsilon^3 V}} |\partial A| |\partial B| V^{-1} m(\mathbb{E}|B(r_0)|)^2.$$

This gives an upper bound on $S^{(a)}$ fitting the error in the assertion of the lemma. To estimate $S^{(b)}$ we use Lemma 3.13 to bound $\mathbf{P}_{A,B}(z_2 \xleftarrow{P[m_0, r_0]} u)$ and $\mathbf{P}_{A,B}(z_2 \xleftarrow{P[m_0, r_0]} z_1)$. This gives

$$S^{(b)} \leq C \frac{(\mathbb{E}|B(r_0)|)^2}{V^2} \sum_{\substack{(a,b) \in \partial A \times \partial B, (u, u'), \\ z_1, z_2, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xleftrightarrow{m_0} z_2) \mathbf{P}_B(b \xleftrightarrow{t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{r_0 - t_1} u').$$

We now sum over (u, u') , z_1, z_2 and t_1 using Lemma 4.4. We get that

$$S^{(b)} \leq C |\partial A| |\partial B| V^{-2} m(\mathbb{E}|B(r_0)|)^2 r_0 m_0 \varepsilon^{-1} (1 + \varepsilon)^{r_0} \leq \frac{C m_0 \varepsilon \alpha_V^{1/2}}{\sqrt{\varepsilon^3 V}} C |\partial A| |\partial B| V^{-1} m(\mathbb{E}|B(r_0)|)^2,$$

by Theorem 4.5 and (2.8). Since $m_0 = o(\varepsilon^{-1})$, this fits within the error estimate in the assertion of the lemma. The estimate on $S^{(c)}$ is performed in precisely the same as for $S^{(b)}$, and gives the same error estimate, concluding the proof. \square

Lemma 6.11. *The following bounds hold:*

$$\sum_{\substack{(a,b) \in \partial A \times \partial B, a' \in \partial A \\ (u, u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xleftrightarrow{P[2m_0, r_0]} u) \mathbf{P}_{A,B}(a' \xleftrightarrow{r_0} z_1) \mathbf{P}_B(b \xleftrightarrow{t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{r_0 - t_1} u') \leq \alpha_V^{1/2} \varepsilon |\partial A|^2 |\partial B| V^{-1} m(\mathbb{E}|B(r_0)|)^2,$$

and

$$\sum_{\substack{(a,b) \in \partial A \times \partial B, a' \in \partial A \\ (u, u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xleftrightarrow{P[2m_0, r_0]} u) \mathbf{P}_{A,B}(a' \xleftrightarrow{r_0} z_1) \mathbf{P}_B(b \xleftrightarrow{r_0 - t_1} z_1) \mathbf{P}_B(z_1 \xleftrightarrow{t_1} u') \leq \alpha_V^{1/2} \varepsilon |\partial A|^2 |\partial B| V^{-1} m(\mathbb{E}|B(r_0)|)^2.$$

Proof. The proof of the second assertion is identical to the first, so we only prove the first. We use Lemma 3.15 to bound $\mathbf{P}_{A,B}(a \xleftrightarrow{P[2m_0, r_0]} u) \leq C V^{-1} \mathbb{E}|B(r_0)|$ and $\mathbf{P}_B(b \xleftrightarrow{t_1} z_1) \leq C V^{-1} (1 + \varepsilon)^{t_1}$. We then sum $\mathbf{P}_B(z_1 \xleftrightarrow{r_0 - t_1} u')$ over (u, u') to obtain a factor of $C m \varepsilon^{-1} (1 + \varepsilon)^{r_0 - t_1}$ by Lemma 4.4. We now sum $\mathbf{P}_{A,B}(a' \xleftrightarrow{r_0} z_1)$ over z_1 and get another $\mathbb{E}|B(r_0)|$ factor and now sum all this over a, b, a', t_1 . This gives a contribution of

$$C |\partial A|^2 |\partial B| V^{-2} m r_0 (\mathbb{E}|B(r_0)|)^3,$$

by Theorem 4.5. This is at most

$$\frac{C \varepsilon |\partial A| \alpha_V^{1/2} \log(\varepsilon^3 V)}{\sqrt{\varepsilon^3 V}} |\partial A| |\partial B| V^{-1} m(\mathbb{E}|B(r_0)|)^2,$$

by our choice of r_0 in (2.8) and Lemma 4.4, concluding our proof. \square

Lemma 6.12. *The following bounds hold:*

$$\sum_{\substack{a, b \in \partial A \times \partial B \\ (u, u'), z_1 \in B, t_1 \in [m_0, r_0]}} \mathbf{P}_A(a \xleftrightarrow{t_1} z_1) \mathbf{P}_A(z_1 \xleftrightarrow{r_0 - t_1} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u') \leq C |\partial A| |\partial B| |B| V^{-2} m r_0 (\mathbb{E}|B(r_0)|)^2,$$

and

$$\sum_{\substack{a, b \in \partial A \times \partial B \\ (u, u'), z_1 \in B, t_1 \in [m_0, r_0]}} \mathbf{P}_A(a \xleftrightarrow{r_0 - t_1} z_1) \mathbf{P}_A(z_1 \xleftrightarrow{t_1} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u') \leq C |\partial A| |\partial B| |B| V^{-2} m r_0 (\mathbb{E}|B(r_0)|)^2.$$

Proof. The proof of the second assertion is identical to the first so we only prove the first. We use Lemma 3.13 to bound

$$\mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u') \leq (1 + o(1))V^{-1}\mathbb{E}|B(r_0)|,$$

and, as before, we use Lemma 3.12 together with Lemma 4.4 to bound

$$\mathbf{P}_A(a \xleftrightarrow{t_1} z_1) \leq CV^{-1}(1 + \varepsilon)^{t_1},$$

sum over u' such that $(u, u') \in E(G)$, and finally use Lemma 4.4 to bound

$$\sum_u \mathbf{P}_A(z_1 \xleftrightarrow{r_0 - t_1} u) \leq C\varepsilon^{-1}(1 + \varepsilon)^{r_0 - t_1}.$$

Altogether, after summing over $a \in \partial A$, $b \in \partial B$, $z_1 \in B$, $t_1 \leq r_0$, this gives the bound of

$$C|\partial A||\partial B||B|V^{-2}mr_0\varepsilon^{-1}(1 + \varepsilon)^{r_0}\mathbb{E}|B(r_0)| \leq C|\partial A||\partial B||B|V^{-2}mr_0(\mathbb{E}|B(r_0)|)^2,$$

where we have used Theorem 4.5. □

Lemma 6.13. *For any positive $\delta > 0$ and $\beta > 0$,*

$$\mathbb{E}_{A,B}S_{j_x, j_y, r_0}(x, y) \geq (1 - 8\beta^{1/2})V^{-1}m(\mathbb{E}|B(r_0)|)^2(|\partial A| - \varepsilon^{-1})(|\partial B| - \varepsilon^{-1}) - \text{Err},$$

where

$$\text{Err} \leq C|\partial A||\partial B|V^{-1}m(\mathbb{E}|B(r_0)|)^2 \left[r_0(|A| + |B|)V^{-1} + \alpha_V^{1/2}(1 + \varepsilon|\partial A|) \right].$$

Proof. We have that

$$\mathbb{E}_{A,B}S_{j_x, j_y, r_0}(x, y) = \sum_{(a,b) \in \partial A \times \partial B} \sum_{(u, u')} \mathbf{P}_{A,B}(\{a \xleftrightarrow{P[2m_0, r_0], x} u\} \text{ and } \{b \xleftrightarrow{P[2m_0, r_0], y} u' \text{ off } B_x(j_x + r_0)\}), \quad (6.9)$$

because the additional requirement that a and b are pivots in the definitions of $\{a \xleftrightarrow{P[2m_0, r_0], x} u\}$ and $\{b \xleftrightarrow{P[2m_0, r_0], y} u'\}$ implies that they are unique in $\partial A \times \partial B$, so no pair (a, b) is overcounted in the sum. We define $B_{\partial A}(r_0; A \cup B) = \cup_{a' \in \partial A} B_{a'}(r_0; A \cup B)$. We condition on $B_{\partial A}(r_0; A \cup B) = H$ for an admissible H (that is, any H that has positive probability and $a \xleftrightarrow{P[2m_0, r_0], x} u$ off B occurs in it). Each summand in (6.9) equals

$$\sum_H \mathbf{P}_{A,B}(B_{\partial A}(r_0; A \cup B) = H) \mathbf{P}_{A,B}(b \xleftrightarrow{P[2m_0, r_0], y} u' \text{ off } H \mid B_{\partial A}(r_0; A \cup B) = H),$$

and we have

$$\mathbf{P}_{A,B}(b \xleftrightarrow{P[2m_0, r_0], y} u' \text{ off } H \mid B_{\partial A}(r_0; A \cup B) = H) = \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u' \text{ off } A \cup H),$$

because in both sides the status of the edges touching $A \cup H$ cannot change the occurrence of the event. This gives that

$$\mathbb{E}_{A,B}S_{j_x, j_y, r_0}(x, y) = \sum_{(a,b) \in \partial A \times \partial B} \sum_{(u, u')} \sum_H \mathbf{P}_{A,B}(B_{\partial A}(r_0; A \cup B) = H) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u' \text{ off } A \cup H).$$

Now, by Claim 3.1,

$$\mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u' \text{ off } A \cup H) \geq \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u') - \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u' \text{ only on } A \cup H),$$

where in the last term we have dropped the requirement that y is pivotal (which only increases the probability). Hence by summing on H we get,

$$\mathbb{E}_{A,B}S_{j_x, j_y, r_0}(x, y) \geq \sum_{(a,b) \in \partial A \times \partial B} \sum_{(u, u')} \mathbf{P}_{A,B}(a \xleftrightarrow{P[2m_0, r_0], x} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u') - S_2,$$

where

$$S_2 = \sum_{(a,b) \in \partial A \times \partial B} \sum_{(u,u')} \sum_H \mathbf{P}_{A,B}(B_{\partial A}(r_0; A \cup B) = H) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u' \text{ only on } A \cup H). \quad (6.10)$$

As before,

$$\mathbf{P}_{A,B}(a \xleftrightarrow{P[2m_0, r_0], x} u) = \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u \text{ off } B),$$

since the status of the edges touching $A \cup B$ in both sides does not matter. Claim 3.1 again gives that

$$\mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u \text{ off } B) \geq \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) - \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0]} u \text{ only on } B),$$

and so we may further expand

$$\mathbb{E}_{A,B} S_{j_x, j_y, r_0}(x, y) \geq S_1 - S_2 - S_3,$$

with

$$S_1 = \sum_{(a,b) \in \partial A \times \partial B} \sum_{(u,u')} \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0], x} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0], y} u'),$$

$$S_3 = \sum_{(a,b) \in \partial A \times \partial B} \sum_{(u,u')} \mathbf{P}_A(a \xleftrightarrow{P[2m_0, r_0]} u \text{ only on } B) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u'),$$

and S_2 is defined in (6.10). Lemma 6.9 gives the required lower bound on S_1 which yields the positive contribution in the assertion of this lemma. We now bound S_2 and S_3 from above, starting with S_3 . If $a \xleftrightarrow{P[2m_0, r_0]} u$ only on B , then either $a \xleftrightarrow{2m_0} u$ or there exists $z_1 \in B$ and $t_1 \in [m_0, r_0]$ such that

$$\{a \xleftrightarrow{=t_1} z_1\} \circ \{z_1 \xleftrightarrow{r_0-t_1} u\} \quad \text{or} \quad \{a \xleftrightarrow{r_0-t_1} z_1\} \circ \{z_1 \xleftrightarrow{=t_1} u\},$$

Indeed, let γ be the lexicographically first shortest path between a and u . If $|\gamma| \leq 2m_0$, then $a \xleftrightarrow{2m_0} u$, otherwise $|\gamma| \in [2m_0, r_0]$ and we take z_1 to be the first vertex in B visited by γ and t is such that $\gamma(t) = z_1$. If $t \geq m_0$, then we put $t_1 = t$ and otherwise we put $t_1 = |\gamma| - t$. In any case $t_1 \in [m_0, r_0]$. When $t \geq m_0$, the witness for $a \xleftrightarrow{=t_1} z_1$ is the set of open edges of the path $\gamma[0, t]$ together with all the closed edges of the graph and the witness for $z_1 \xleftrightarrow{r_0-t_1} u$ are the open edges of $\gamma[t, |\gamma|]$. The case $t \leq m_0$ is done similarly. We get that

$$\begin{aligned} S_3 &\leq \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u')}} \mathbf{P}_A(a \xleftrightarrow{2m_0} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u') \\ &+ \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1 \in B, t_1 \in [m_0, r_0]}} \mathbf{P}_A(a \xleftrightarrow{=t_1} z_1) \mathbf{P}_A(z_1 \xleftrightarrow{r_0-t_1} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u') \\ &+ \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1 \in B, t_1 \in [m_0, r_0]}} \mathbf{P}_A(a \xleftrightarrow{r_0-t_1} z_1) \mathbf{P}_A(z_1 \xleftrightarrow{=t_1} u) \mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u'). \end{aligned}$$

For the first term we bound $\mathbf{P}_B(b \xleftrightarrow{P[2m_0, r_0]} u') \leq CV^{-1} \mathbb{E}|B(r_0)|$ by Lemma 3.13 and sum over everything to get a contribution bounded by

$$\begin{aligned} C|\partial A||\partial B| m V^{-1} \mathbb{E}|B(r_0)| m_0 &\leq C|\partial A||\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2 [m_0 (\mathbb{E}|B(r_0)|)^{-1}] \\ &\leq C\alpha_V^{1/2} |\partial A||\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2, \end{aligned} \quad (6.11)$$

by our choice of r_0 in (2.8), our assumptions $\alpha_V \geq (\varepsilon^3 V)^{-1/2}$ in (2.5) and $m_0 = o(\varepsilon^{-1})$ and Corollary 4.6. This fits in the second term of Err in the assertion of the lemma. We bound the second and third terms using Lemma 6.12 giving an upper bound of

$$C|\partial A||\partial B||B| V^{-2} m r_0 (\mathbb{E}|B(r_0)|)^2,$$

which fits in the first term of Err in the assertion of the lemma.

We proceed to bound S_2 in (6.10) from above. As before, if $b \xrightarrow{P[2m_0, r_0]} u'$ only on $H \cup A$, then either $b \xrightarrow{2m_0} u'$ or there exists $z_1 \in H \cup A$ and $t_1 \in [m_0, r_0]$ such that

$$\{b \xrightarrow{=t_1} z_1\} \circ \{z_1 \xrightarrow{r_0-t_1} u'\} \quad \text{or} \quad \{b \xrightarrow{r_0-t_1} z_1\} \circ \{z_1 \xrightarrow{=t_1} u'\}. \quad (6.12)$$

The case $b \xrightarrow{2m_0} u'$ is handled as before and gives a contribution of $C|\partial A||\partial B|mV^{-1}\mathbb{E}|B(r_0)|m_0$ which by (6.11) again fits the second term of Err. To handle the other cases, let us first sum the contribution to S_2 due to (6.12) over $z_1 \in H$. We use the BK-Reimer inequality and change order of summation to bound this contribution to S_2 by

$$\begin{aligned} & \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u, \exists a' \in \partial A \text{ such that } a' \xrightarrow{r_0} z_1) \mathbf{P}_B(b \xrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{r_0-t_1} u') \\ & + \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1, t_1 \leq r_0}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u, \exists a' \in \partial A \text{ such that } a' \xrightarrow{r_0} z_1) \mathbf{P}_B(b \xrightarrow{r_0-t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{=t_1} u'). \end{aligned}$$

Now, if $a \xrightarrow{P[2m_0, r_0]} u$ and there exists $a' \in \partial A$ with $a' \xrightarrow{r_0} z_1$, then either $a \xrightarrow{P[2m_0, r_0]} u, a \xrightarrow{r_0} z_1$ or there exists $a' \in \partial A$ such that $\{a \xrightarrow{P[2m_0, r_0]} u\} \circ \{a' \xrightarrow{r_0} z_1\}$. Hence we may bound this from above by (I) + (II) where

$$\begin{aligned} (I) &= \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u, a \xrightarrow{r_0} z_1) \mathbf{P}_B(b \xrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{r_0-t_1} u') \\ & + \sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1, t_1 \leq r_0}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u, a \xrightarrow{r_0} z_1) \mathbf{P}_B(b \xrightarrow{r_0-t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{=t_1} u'), \end{aligned}$$

and

$$\begin{aligned} (II) &= \sum_{\substack{(a,b) \in \partial A \times \partial B, a' \in \partial A \\ (u,u'), z_1, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u) \mathbf{P}_{A,B}(a' \xrightarrow{r_0} z_1) \mathbf{P}_B(b \xrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{r_0-t_1} u') \\ & + \sum_{\substack{(a,b) \in \partial A \times \partial B, a' \in \partial A \\ (u,u'), z_1, t_1 \leq r_0}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u) \mathbf{P}_{A,B}(a' \xrightarrow{r_0} z_1) \mathbf{P}_B(b \xrightarrow{r_0-t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{=t_1} u'). \end{aligned}$$

Lemma 6.10 readily gives that (I) $\leq \alpha_V^{1/2} |\partial A| |\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2$ which fits into the second term of Err. Lemma 6.11 gives that (II) $\leq \alpha_V^{1/2} \varepsilon |\partial A|^2 |\partial B| V^{-1} m (\mathbb{E}|B(r_0)|)^2$ which fits in the second term of Err. We sum the contribution to S_2 due to (6.12) over $z_1 \in A$ and bound it from above by

$$\sum_{\substack{(a,b) \in \partial A \times \partial B \\ (u,u'), z_1 \in A, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \xrightarrow{P[2m_0, r_0]} u) \mathbf{P}_B(b \xrightarrow{=t_1} z_1) \mathbf{P}_B(z_1 \xrightarrow{r_0-t_1} u') \leq C|\partial A||\partial B||A|V^{-2}mr_0(\mathbb{E}|B(r_0)|)^2,$$

by an appeal to Lemma 6.12. This fits in the first term of Err and concludes our proof. \square

Lemma 6.14. *The following bound holds:*

$$\mathbb{E}_{A,B} S_{j_x, j_y, r_0}(x, y)^2 \mathbf{1}_{\{\partial A \neq \partial B\}} \leq Q_1 + Q_2 + Q_3,$$

where

$$\begin{aligned} Q_1 &= (1 + O(\alpha_V + \varepsilon m_0)) V^{-2} m^2 (\mathbb{E}|B(r_0)|)^4 |\partial A|^2 |\partial B|^2, \\ Q_2 &= CV^{-2} m^2 \varepsilon^{-1} (\mathbb{E}|B(r_0)|)^4 |\partial A| |\partial B| (|\partial A| + |\partial B|), \\ Q_3 &= CV^{-2} m^2 \varepsilon^{-2} (\mathbb{E}|B(r_0)|)^4 |\partial A| |\partial B|. \end{aligned}$$

Proof. Assume that (u_1, u'_1) and (u_2, u'_2) are two edges and let a, a_1, a_2 be vertices in ∂A and b, b_1, b_2 vertices in ∂B . Define

$$\mathcal{T}(u_1, u_2, a_1, a_2) = \{a_1 \xleftrightarrow{P[2m_0, r_0]} u_1\} \circ \{a_2 \xleftrightarrow{P[2m_0, r_0]} u_2\}, \quad \mathcal{T}(u_1, u_2, a) = \{a \xleftrightarrow{P[2m_0, r_0]} u_1\} \cap \{a \xleftrightarrow{P[2m_0, r_0]} u_2\}. \quad (6.13)$$

We define $\mathcal{T}(u'_1, u'_2, b_1, b_2)$ and $\mathcal{T}(u'_1, u'_2, b)$ in a similar fashion.

Now, if (u_1, u'_1) and (u_2, u'_2) are counted in $S_{j_x, j_y, r_0}(x, y)^2 \mathbf{1}_{\{\partial A \not\leftrightarrow \partial B\}^{2r_0}}$, then one of the following events must occur off $A \cup B$:

- (1) There exists a_1, a_2, b_1, b_2 such that $\mathcal{T}(u_1, u_2, a_1, a_2) \circ \mathcal{T}(u'_1, u'_2, b_1, b_2)$ occurs,
- (2) There exists a_1, a_2, b such that $\mathcal{T}(u_1, u_2, a_1, a_2) \circ \mathcal{T}(u'_1, u'_2, b)$ occurs, or the symmetric case $\mathcal{T}(u_1, u_2, a) \circ \mathcal{T}(u'_1, u'_2, b_1, b_2)$.
- (3) There exists a, b such that $\mathcal{T}(u_1, u_2, a) \circ \mathcal{T}(u'_1, u'_2, b)$ occurs.

See Figure 5. Observe that the disjoint occurrence of the events is implied since $\partial A \not\leftrightarrow \partial B$. We now sum the probability of these events over $(u_1, u'_1), (u_2, u'_2)$ and this gives us three terms which we will bound by Q_1, Q_2 and Q_3 , respectively. By Lemma 3.13 and the BK inequality,

$$\mathbf{P}_{A,B}(\mathcal{T}(u_1, u_2, a_1, a_2)) \leq \frac{(1 + O(\alpha_V + \varepsilon m_0))(\mathbb{E}|B(r_0)|)^2}{V^2}, \quad (6.14)$$

whence

$$\sum_{\substack{a_1, a_2, b_1, b_2, \\ (u_1, u'_1), (u_2, u'_2)}} \mathbf{P}_{A,B}(\mathcal{T}(u_1, u_2, a_1, a_2) \circ \mathcal{T}(u'_1, u'_2, b_1, b_2)) \leq (1 + O(\alpha_V + \varepsilon m_0))V^{-2}m^2(\mathbb{E}|B(r_0)|)^4|\partial A|^2|\partial B|^2,$$

which equals Q_1 . To bound the probability of (2), if $\mathcal{T}(u'_1, u'_2, b)$ occurs, then, as before, there exists a vertex z_1 and $t_1 \in [m_0, r_0]$ such that

$$\{b \xleftrightarrow{=t_1} z_1\} \circ \{z_1 \xleftrightarrow{r_0-t_1} u'_1\} \circ \{z_1 \xleftrightarrow{r_0-t_1} u'_2\},$$

or there exists z_1 such that

$$\{b \xleftrightarrow{m_0} z_1\} \circ \{z_1 \xleftrightarrow{P[m_0, r_0]} u'_1\} \circ \{z_1 \xleftrightarrow{P[m_0, r_0]} u'_2\},$$

or there exists z_1 such that

$$\{b \xleftrightarrow{P[m_0, r_0]} z_1\} \circ \{z_1 \xleftrightarrow{P[m_0, r_0]} u'_1\} \circ \{z_1 \xleftrightarrow{m_0} u'_2\}.$$

Hence, the BK-Reimer inequality gives that

$$\begin{aligned} \sum_{u'_1, u'_2} \mathbf{P}_{A,B}(\mathcal{T}(u'_1, u'_2, b)) &\leq \sum_{\substack{u'_1, u'_2, z_1, \\ t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(b \xleftrightarrow{=t_1} z_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{r_0-t_1} u'_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{r_0-t_1} u'_2) \\ &\quad + \sum_{u'_1, u'_2, z_1} \mathbf{P}_{A,B}(b \xleftrightarrow{m_0} z_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{P[m_0, r_0]} u'_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{P[m_0, r_0]} u'_2) \\ &\quad + \sum_{u'_1, u'_2, z_1} \mathbf{P}_{A,B}(b \xleftrightarrow{P[m_0, r_0]} z_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{P[m_0, r_0]} u'_1) \mathbf{P}_{A,B}(z_1 \xleftrightarrow{m_0} u'_2). \end{aligned}$$

We estimate the first sum by summing on u'_2, u'_1 then on z_1, t_1 using Lemma 4.4 to get a bound of

$$C\varepsilon^{-3}(1 + \varepsilon)^{2r_0} \leq C\varepsilon^{-1}(\mathbb{E}|B(r_0)|)^2,$$

by Theorem 4.5. The second and third sums are bounded by $Cm_0(\mathbb{E}|B(r_0)|)^2$ which is of lower order since $\varepsilon m_0 = o(1)$ by (2.9). We use the BK inequality and (6.14) to bound the contribution due to the

FIGURE 5. The three contributions to the second moment of $S_{j_x, j_y, r_0}(x, y)$. The main contribution comes from (1).

first event in (2) by

$$\sum_{\substack{a_1, a_2, b, (u_1, u_1'), \\ (u_2, u_2')}} \mathbf{P}_{A,B}(\mathcal{T}(u_1, u_2, a_1, a_2)) \mathbf{P}_{A,B}(\mathcal{T}(u_1', u_2', b)) \leq CV^{-2} m^2 \varepsilon^{-1} (\mathbb{E}|B(r_0)|)^4 |\partial A|^2 |\partial B|.$$

The symmetric in (2) obeys the same bound with the roles of $|\partial A|$ and $|\partial B|$ reversed. This contribution equals Q_2 . To bound the contribution due to (3), we note that

$$\sum_{a, b, (u_1, u_1'), (u_2, u_2')} \mathbf{P}_{A,B}(\mathcal{T}(u_1, u_2, a)) \mathbf{P}_{A,B}(\mathcal{T}(u_1', u_2', b)),$$

is bounded using the BK-Reimer inequality by the three sums

$$\sum_{\substack{a, b, (u_1, u_1'), (u_2, u_2') \\ z_1, z_2, t_1, t_2 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \stackrel{=t_1}{\longleftrightarrow} z_1) \mathbf{P}_{A,B}(z_1 \stackrel{r_0-t_1}{\longleftrightarrow} u_1) \mathbf{P}_{A,B}(z_1 \stackrel{r_0-t_1}{\longleftrightarrow} u_2) \mathbf{P}_{A,B}(b \stackrel{=t_2}{\longleftrightarrow} z_2) \mathbf{P}_{A,B}(z_2 \stackrel{r_0-t_2}{\longleftrightarrow} u_1') \mathbf{P}_{A,B}(z_2 \stackrel{r_0-t_2}{\longleftrightarrow} u_2'),$$

$$\sum_{\substack{a, b, (u_1, u_1'), (u_2, u_2') \\ z_1, z_2, t_1 \in [m_0, r_0]}} \mathbf{P}_{A,B}(a \stackrel{=t_1}{\longleftrightarrow} z_1) \mathbf{P}_{A,B}(z_1 \stackrel{r_0-t_1}{\longleftrightarrow} u_1) \mathbf{P}_{A,B}(z_1 \stackrel{r_0-t_1}{\longleftrightarrow} u_2) \mathbf{P}_{A,B}(b \stackrel{m_0}{\longleftrightarrow} z_2) \mathbf{P}_{A,B}(z_2 \stackrel{P[m_0, r_0]}{\longleftrightarrow} u_1') \mathbf{P}_{A,B}(z_2 \stackrel{P[m_0, r_0]}{\longleftrightarrow} u_2'),$$

and

$$\sum_{\substack{a, b, (u_1, u_1') \\ (u_2, u_2'), z_1, z_2}} \mathbf{P}_{A,B}(a \stackrel{m_0}{\longleftrightarrow} z_1) \mathbf{P}_{A,B}(z_1 \stackrel{P[m_0, r_0]}{\longleftrightarrow} u_1) \mathbf{P}_{A,B}(z_1 \stackrel{P[m_0, r_0]}{\longleftrightarrow} u_2) \mathbf{P}_{A,B}(b \stackrel{m_0}{\longleftrightarrow} z_2) \mathbf{P}_{A,B}(z_2 \stackrel{P[m_0, r_0]}{\longleftrightarrow} u_1') \mathbf{P}_{A,B}(z_2 \stackrel{P[m_0, r_0]}{\longleftrightarrow} u_2').$$

To bound the first sum, we use Lemma 3.12 and Lemma 4.4 to bound $\mathbf{P}_{A,B}(a \stackrel{=t_1}{\longleftrightarrow} z_1) \leq CV^{-1}(1+\varepsilon)^{t_1}$ and $\mathbf{P}_{A,B}(b \stackrel{=t_2}{\longleftrightarrow} z_2) \leq CV^{-1}(1+\varepsilon)^{t_2}$. We then use Lemma 3.19 and Lemma 4.4 to sum over $z_1, z_2, (u_1, u_1'), (u_2, u_2')$. This gives us an upper bound of

$$\begin{aligned} & CV^{-2} |\partial A| |\partial B| m^2 \varepsilon^{-6} (1+\varepsilon)^{4r_0} + C |\partial A| |\partial B| V^{-1} m^2 m_0 \alpha_V \sum_{t_1, t_2 \in [m_0, r_0]} (1+\varepsilon)^{t_1+t_2} \\ & \leq CV^{-2} |\partial A| |\partial B| m^2 \varepsilon^{-2} (\mathbb{E}|B(r_0)|)^4, \end{aligned}$$

where the last inequality is due to Theorem 4.5 and our choice of r_0 in (2.8). This is contained in Q_3 . To bound the second sum, we use Lemma 3.15 to bound each of the last two terms by $CV^{-1} \mathbb{E}|B(r_0)|$.

We then sum over (u_1, u'_1) and (u_2, u'_2) using Lemma 4.4. We then sum over z_1, z_2 using Lemma 4.4 and finally over a, b, t_1 to get that this sum is at most

$$C|\partial A||\partial B|V^{-2}m^2(\mathbb{E}|B(r_0)|)^4\varepsilon^{-1}m_0,$$

which is contained in Q_3 since $\varepsilon m_0 = o(1)$. For the third sum we use Lemma 3.15 four times, and then sum over everything to get a bound of

$$C|\partial A||\partial B|V^{-2}m^2(\mathbb{E}|B(r_0)|)^4m_0^2,$$

which is also contained in Q_3 , concluding our proof. \square

Proof of Theorem 6.3. We condition on the events $B_x(j_x) = A$ and $B_y(j_y) = B$ such that the event $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$ holds. By requirement (2) of $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$ and our choice of parameters

$$r_0(|A| + |B|)V^{-1} \leq V^{-1}\varepsilon^{-3}\log(\varepsilon^3 V)e^{3M} \leq (\log \varepsilon^3 V)^{-1},$$

and

$$\alpha_V^{1/2}\varepsilon|\partial A| \leq e^{3M}\alpha_V^{1/2} \leq \alpha_V^{1/4}.$$

Hence the error term in Lemma 6.13 is at most

$$\text{Err} \leq C[(\log \varepsilon^3 V)^{-1} + \alpha_V^{1/4}]|\partial A||\partial B|V^{-1}m(\mathbb{E}|B(r_0)|)^2.$$

Lemma 6.13 together with requirement (5) in the definition of $\mathcal{A}(x, y, j_x, j_y, r_0, \beta, k)$ and our choice of β in (6.1) (in particular, that $\beta \ll \alpha_V^{1/4} \wedge (\log \varepsilon^3 V)^{-1}$ by (2.7)) give

$$\mathbb{E}_{A,B} \left[S_{j_x, j_y, r_0}(x, y) \mathbf{1}_{\substack{2r_0 \\ \{\partial A \neq \partial B\}}} \right] \geq (1 - C\beta^{1/2})V^{-1}m(\mathbb{E}|B(r_0)|)^2|\partial A||\partial B|.$$

Since $|\partial A|$ and $|\partial B|$ are at least $e^{k/4}\varepsilon^{-1}$,

$$\varepsilon^{-1}|\partial A|^2|\partial B| + \varepsilon^{-1}|\partial A||\partial B|^2 + \varepsilon^{-2}|\partial A||\partial B| \leq Ce^{-k/4}|\partial A|^2|\partial B|^2,$$

hence, by Lemma 6.14 and our choice of parameters,

$$\mathbb{E}_{A,B} \left[S_{j_x, j_y, r_0}(x, y)^2 \mathbf{1}_{\substack{2r_0 \\ \{\partial A \neq \partial B\}}} \right] \leq (1 + O(e^{-k/4}))V^{-2}m^2(\mathbb{E}|B(r_0)|)^4|\partial A|^2|\partial B|^2.$$

We conclude that

$$\mathbf{P}_{A,B}(S_{j_x, j_y, r_0}(x, y) \geq 2\beta^{1/2}V^{-1}m(\mathbb{E}|B(r_0)|)^2|\partial A||\partial B|) \geq 1 - O(\beta^{1/2}),$$

where we used the fact that $e^{-k/4} = o(\beta)$ and (4.4). This concludes our proof since $|\partial A|$ and $|\partial B|$ are at least ε^{-1} . \square

7. PROOFS OF MAIN THEOREMS

7.1. Proof of Theorem 1.3. In Section 2.4 we already proved Theorem 1.3(a) hence we may assume that the finite triangle condition (1.5) holds and focus on part (b) of the theorem. Since $|\mathcal{C}_1| \leq k_0 + Z_{\geq k_0}$ where k_0 is from Theorem 2.2, Lemma 2.3 immediately gives that $|\mathcal{C}_1| \leq (2 + o(1))\varepsilon V$ whp, showing the required upper bound on $|\mathcal{C}_1|$ — note that this argument only uses the finite triangle condition hence it is valid for any ε_m satisfying $\varepsilon_m \gg V^{-1/3}$ and $\varepsilon_m = o(1)$. For the lower bound we will additionally assume, as part (b) requires, that $\varepsilon_m = o(m_0^{-1})$ and show that

$$\mathbf{P}_p(|\mathcal{C}_1| \geq (2 - o(1))\varepsilon V) = 1 - o(1). \quad (7.1)$$

This establishes part (b) of Theorem 1.3. Recall that $p = p_c(1 + \varepsilon)$ is our percolation probability, let $\theta > 0$ be an arbitrary small constant and put p_2, p_1 to satisfy

$$p_2 = \theta\varepsilon/m, \quad p_c(1 + \varepsilon) = p_1 + (1 - p_1)p_2,$$

so that $p_c(1 + (1 - \theta)\varepsilon) \leq p_1 \leq p_c(1 + \varepsilon)$ since $p_c \geq 1/m$. Denote by G_{p_1} and G_{p_2} two independent percolation instances of G with parameters p_1 and p_2 , respectively. The sprinkling procedure relies

on the fact that G_p is distributed as $G_{p_1} \cup G_{p_2}$. We first apply Theorem 2.4 to G_{p_1} and deduce that for M, r defined in (2.7) and r_0 defined in (2.8),

$$\mathbf{P}_{p_1}(P_{r,r_0} \geq (1-3\theta)4\epsilon^2 V^2) \geq 1 - o(1). \quad (7.2)$$

Now we wish to show that when we “sprinkle” this configuration in G_{p_1} , that is, when we add to the configuration independent p_2 -open edges, most of these vertices join together to form one cluster of size roughly $2\epsilon V$. To make this formal, given G_{p_1} , we construct an auxiliary simple graph H with vertex set

$$V(H) = \{x \in G_{p_1} : |\mathcal{C}(x)| \geq (\epsilon^3 V)^{1/4} \epsilon^{-2}\},$$

and edge set

$$E(H) = \{(x, y) \in V(H)^2 : x, y \text{ are } (r, r_0)\text{-good}\}.$$

Thus, using Lemma 2.3 with $k_0 = \epsilon^{-2}(\epsilon^3 V)^{1/4}$ and (7.2), with probability at least $1 - o(1)$,

$$|V(H)| = (2 + o(1))\epsilon V, \quad |E(H)| \geq (1 - 3\theta)4\epsilon^2 V^2. \quad (7.3)$$

Denote $\nu = |V(H)|$ and write x_1, \dots, x_ν for the vertices in G_{p_1} corresponding to those of H . Given G_{p_1} for which the event in (7.3) occurs, we will show that whp in $G_{p_1} \cup G_{p_2}$ there is no way to partition the set of vertices into $M_1 \uplus M_2 = \{x_1, \dots, x_\nu\}$ with $|M_1| \geq 3\theta\nu$ and $|M_2| \geq 3\theta\nu$ such that there is no open path in $G_{p_1} \cup G_{p_2}$ connecting a vertex in M_1 with a vertex in M_2 . This implies that whp the largest connected component in $G_{p_1} \cup G_{p_2}$ is of size at least $(1 - 3\theta)\nu$.

To show this, we first claim that the number of such partitions is at most $2^{3(\epsilon^3 V)^{3/4}}$ since $|\mathcal{C}(x_i)| \geq (\epsilon^3 V)^{1/4} \epsilon^{-2}$. Secondly, given such a partition, we claim that the number of edges (u, u') such that $u \in M_1$ and $u' \in M_2$ (note that, by definition, these edges must be p_1 -closed) is at least $e^{-40M}(\log M)^{-1}\theta\epsilon^2 V m$. To see this, we consider the set of edges in H for which both sides lie in either M_1 or M_2 (more precisely, the vertices of H corresponding to M_1 and M_2). This number is at most

$$M_1^2 + M_2^2 \leq (3\theta\nu)^2 + (1 - 3\theta)^2 \nu^2 \leq (1 - 5\theta)\nu^2,$$

where we used the fact that $\theta > 0$ is a small enough constant, $M_1 + M_2 = \nu$ and both M_1 and M_2 are in $[3\theta\nu, (1 - 3\theta)\nu]$. By (7.3), the number of edges in H such that one end is in M_1 and the other in M_2 is at least $\theta\epsilon^2 V^2$. In other words, there are at least $\theta\epsilon^2 V^2$ pairs $(x, y) \in M_1 \times M_2$ such that $S_{2r+r_0}(x, y) \geq (\log M)^{-1} V^{-1} m \epsilon^{-2} (|B(r_0)|)^2$. Note that is a large number due to our condition (2.8). In total, we counted at least $\theta\epsilon^2 V^2 \cdot (\log M)^{-1} V^{-1} m \epsilon^{-2} (|B(r_0)|)^2$ edges (u, u') and no edge is counted more than $|B_u(2r + r_0)| \cdot |B_{u'}(2r + r_0)|$ times, which is at most $e^{40M} \epsilon^{-2} (|B(r_0)|)^2$ by the definition of $S_{2r+r_0}(x, y)$ and the second claim follows.

Hence, if $|\mathcal{C}_1| \leq (1 - 3\theta)\nu$, then there exists such a partition in which all of the above edges (u, u') are p_2 -closed. By the two claims above, the probability of this is at most

$$2^{3(\epsilon^3 V)^{3/4}} (1 - p_2) e^{-40M} (\log M)^{-1} \theta m \epsilon^2 V \leq 2^{3(\epsilon^3 V)^{3/4}} e^{-e^{-40M} (\log M)^{-1} \theta^2 \epsilon^3 V} = o(1),$$

since $p_2 = \theta\epsilon/m$ and by our choice of parameters in (2.7) and (2.9). This concludes the proof of (7.1) since $\theta > 0$ was arbitrary and establishes the required estimate on $|\mathcal{C}_1|$ of Theorem 1.3 (b).

We now use (7.1) to show the required bounds on $\mathbb{E}|\mathcal{C}(0)|$ and $|\mathcal{C}_2|$. The upper bound $\mathbb{E}|\mathcal{C}(0)| \leq (4 + o(1))\epsilon^2 V$ is stated in Lemma 2.3 and the lower bound follows immediately from our estimate on \mathcal{C}_1 . Indeed, write \mathcal{C}_j for the j th largest component. Then

$$\mathbb{E}|\mathcal{C}(0)| = V^{-1} \sum_{v \in V(G)} \mathbb{E}|\mathcal{C}(v)| = V^{-1} \sum_{j \geq 1} \mathbb{E}|\mathcal{C}_j|^2 \geq V^{-1} \mathbb{E}|\mathcal{C}_1|^2 \geq (4 - o(1))\epsilon^2 V,$$

where the first equality is by transitivity, the second equality is because each component \mathcal{C}_j is counted $|\mathcal{C}_j|$ times in the sum on the left and the last inequality is due to (7.1). Furthermore, by this inequality

and Lemma 2.3, we deduce that

$$\sum_{j \geq 2} \mathbb{E} |\mathcal{C}_j|^2 = o(\varepsilon^2 V^2),$$

and hence $|\mathcal{C}_2| = o(\varepsilon V)$ whp. This concludes the proof of Theorem 1.3. \square

7.2. Proof of Theorem 1.1. In this section we restrict our attention to the hypercube and prove Theorem 1.1. We begin by showing that m_0 , defined in Theorem 1.3 with $\alpha_V = m^{-1} \log m$, satisfies $m_0 = O(m \log m)$. See Lemma 7.1. The proof of Theorem 1.1 is then split into two cases. In the first case we assume that $\varepsilon_m \leq 1/m^2$ so that $\varepsilon = o(m_0^{-1})$ and appeal to Theorem 1.3. In the second case we perform the classical sprinkling argument for the case $\varepsilon \geq 1/m^2$, as done in [18].

Lemma 7.1 (NBW estimates). *On the hypercube $\{0, 1\}^m$*

$$T_{\text{mix}}(m^{-1} \log m) = O(m \log m),$$

and for any integer $L \geq 1$

$$\sup_{x,y} \sum_{u,v} \sum_{\substack{t_1, t_2, t_3=0 \\ t_1+t_2+t_3 \geq 3}}^L \mathbf{p}^{t_1}(x, u) \mathbf{p}^{t_2}(u, v) \mathbf{p}^{t_3}(v, y) \leq O(1/m^2) + O(L^3/V). \quad (7.4)$$

Proof. We make use of the results in [25], as we explain now. The bound on $T_{\text{mix}}(m^{-1} \log m) = O(m \log m)$ is [25, Theorem 3.5]. We next explain how to prove (7.4), which will give condition (3) in Theorem 1.3 for $L = Am \log m$ and an appropriate $A > 0$.

Let $D: \{0, 1\}^m \rightarrow [0, 1]$ be the simple random walk transition probability on the hypercube, that is, $D(v) = 1/m$ whenever v is a neighbor of the all zero vector. Our proof of (7.4) relies on Fourier theory. For convenience, we take the Fourier dual of $\{0, 1\}^m$ to be $\{0, 1\}^m$. Then, the Fourier transform $\hat{f}(k)$ of $f: \{0, 1\}^m \rightarrow \mathbb{R}$ is given by

$$\hat{f}(k) = \sum_{x \in \{0, 1\}^m} (-1)^{x \cdot k} f(x), \quad (7.5)$$

with inverse Fourier transform

$$f(x) = \frac{1}{V} \sum_{k \in \{0, 1\}^m} (-1)^{x \cdot k} \hat{f}(k). \quad (7.6)$$

For the hypercube, $\hat{D}(k)$ takes the appealingly simple form

$$\hat{D}(k) = 1 - 2a(k)/m, \quad (7.7)$$

where $a(k)$ is the number of non-zero coordinates of k .

In [25, Theorem 3.5] it is proved that, when $m \geq 2$ and $t \geq 1$, with $\hat{\mathbf{p}}^t(k)$ denoting the Fourier transform of $x \mapsto \mathbf{p}^t(0, x)$,

$$|\hat{\mathbf{p}}^t(k)| \leq \max(|\hat{D}(k)|, 1/\sqrt{m-1})^{t-1}, \quad (7.8)$$

and $\hat{\mathbf{p}}^0(k) = 1$. This gives us all the necessary bounds to prove the NBW triangle condition (7.4).

Denote the sum in (7.4) by S . The contribution to S where $t_1 + t_2 + t_3 = 3$ equals $O(1/m^2)$. Thus, we are left to bound the contribution due to t_1, t_2, t_3 with $t_1 + t_2 + t_3 \geq 4$. For any $t \geq 1$,

$$\mathbf{p}^t(x, y) \leq \frac{m}{m-1} (D * \mathbf{p}^{t-1})(x, y), \quad (7.9)$$

where, for $f, g: \{0, 1\}^m \rightarrow \mathbb{R}$, we define the convolution $f * g$ by

$$(f * g)(x) = \sum_{y \in \{0, 1\}^m} f(y) g(x - y). \quad (7.10)$$

Therefore,

$$S \leq C/m^2 + 3^4 \left(\frac{m}{m-1}\right)^4 \sup_{x,y} \sum_{\substack{s_1, s_2, s_3=0 \\ s_1+s_2+s_3 \geq 0}}^L (D^{*4} * \mathbf{p}^{s_1} * \mathbf{p}^{s_2} * \mathbf{p}^{s_3})(x, y), \quad (7.11)$$

where 3^4 is an upper bound on the number of ways we can add 4 to the coordinates of (s_1, s_2, s_3) to get (t_1, t_2, t_3) with $t_1 + t_2 + t_3 \geq 4$. The above can be bounded in terms of Fourier transforms as

$$\begin{aligned} S &\leq C/m^2 + \frac{C}{V} \sup_{x,y} \sum_{k \in \{0,1\}^m} (-1)^{k \cdot (y-x)} \sum_{\substack{s_1, s_2, s_3=0 \\ s_1+s_2+s_3 \geq 0}}^L \hat{D}(k)^4 \hat{\mathbf{p}}^{s_1}(k) \hat{\mathbf{p}}^{s_2}(k) \hat{\mathbf{p}}^{s_3}(k) \\ &\leq C/m^2 + \frac{C}{V} \sum_{k \in \{0,1\}^m} \sum_{\substack{s_1, s_2, s_3=0 \\ s_1+s_2+s_3 \geq 0}}^L \hat{D}(k)^4 |\hat{\mathbf{p}}^{s_1}(k)| |\hat{\mathbf{p}}^{s_2}(k)| |\hat{\mathbf{p}}^{s_3}(k)|. \end{aligned} \quad (7.12)$$

The contribution to $k = 0$ equals L^3/V since $\hat{D}(0) = \hat{\mathbf{p}}^{\mathbf{1}}(0) = 1$, and the contribution due to $k = 1$ (where $\mathbf{1}$ denotes the all 1 vector) obeys the same bound. It is not hard to adapt the proof of [17, Proposition 1.2] to show that the sum over $k \neq 0, 1$ is $O(1/m^2)$. We perform the details of this computation now.

Writing $x_+ = \max(x, 0)$ for $x \in \mathbb{R}$, and noting that there are at most 2 values of s for which $(s-1)_+ = t$, we obtain

$$\begin{aligned} S &\leq C/m^2 + 2L^3/V + \frac{C}{V} \sum_{k \in \{0,1\}^m: k \neq 0,1} \sum_{s_1, s_2, s_3=0}^L \hat{D}(k)^4 \max(|\hat{D}(k)|, 1/\sqrt{m-1})^{(s_1-1)_+ + (s_2-1)_+ + (s_3-1)_+} \\ &\leq C/m^2 + 2L^3/V + \frac{C2^3}{V} \sum_{k \in \{0,1\}^m: k \neq 0,1} \hat{D}(k)^4 \sum_{s_1, s_2, s_3=0}^{\infty} \max(|\hat{D}(k)|, 1/\sqrt{m-1})^{s_1+s_2+s_3} \\ &= C/m^2 + 2L^3/V + \frac{C2^3}{V} \sum_{k \in \{0,1\}^m: k \neq 0,1} \frac{\hat{D}(k)^4}{[1 - \max(|\hat{D}(k)|, 1/\sqrt{m-1})]^3}. \end{aligned} \quad (7.13)$$

We bound

$$\begin{aligned} &\frac{1}{V} \sum_{k \in \{0,1\}^m: k \neq 0,1} \frac{\hat{D}(k)^4}{[1 - \max(|\hat{D}(k)|, 1/\sqrt{m-1})]^3} \\ &\leq \frac{1}{V} \sum_{k \in \{0,1\}^m: k \neq 0,1} \hat{D}(k)^4 \left[\frac{1}{[1 - |\hat{D}(k)|]^3} + \frac{1}{[1 - 1/\sqrt{m-1}]^3} \right]. \end{aligned} \quad (7.14)$$

We next use the fact that $\frac{1}{V} \sum_{k \in \{0,1\}^m} \hat{D}(k)^4$ is the probability that a four-step simple random walk on the hypercube returns to its starting point, which is $O(1/m^2)$. Alternatively, and more useful for the proof that follows, we can write

$$\frac{1}{V} \sum_{k \in \{0,1\}^m} \hat{D}(k)^4 = 2^{-m} \sum_{j=0}^m \binom{m}{j} (1 - 2j/m)^4 = m^{-4} \mathbb{E}[(2X - m)^4] = O(1/m^2), \quad (7.15)$$

where X has a binomial distribution with parameters $1/2$ and m , and we use that $\mathbb{E}[(2X - m)^4] = O(m^2)$. We use similar ideas to deal with the contribution involving $[1 - |\hat{D}(k)|]^{-3}$, which we rewrite as

$$\frac{1}{V} \sum_{k \in \{0,1\}^m: k \neq 0,1} \frac{\hat{D}(k)^4}{[1 - |\hat{D}(k)|]^3} = 2^{-m} \sum_{j=1}^{m-1} \binom{m}{j} \frac{(1 - 2j/m)^4}{[(2j/m) \wedge (2 - 2j/m)]^3}. \quad (7.16)$$

The sum $2^{-m} \sum_{j \notin [m/4, 3m/4]} \binom{m}{j}$ is exponentially small in m by either Stirling's formula or large deviation bounds on the binomial distribution with parameters m and $1/2$. When $j \in [m/4, 3m/4]$, we can bound $1/[(2j/m) \wedge (2 - 2j/m)]^3 \leq 8$ to bound the above sum by $O(1/m^2)$ in the same way as in (7.15). Together with (7.13), this completes the proof of (7.4). \square

Proof of Theorem 1.1. We start by proving the theorem in the case $\varepsilon_m \leq 1/m^2$. We take $\alpha_V = m^{-1} \log m$ and Lemma 7.1 shows that $m_0 = O(m \log m)$ and that condition (3) of Theorem 1.3 holds. Condition (2) of Theorem 1.3 holds by (1.2). Condition (1) is fulfilled automatically, therefore, in this case Theorem 1.1 follows from Theorem 1.3.

We now handle the case $\varepsilon \geq 1/m^2$ and $\varepsilon = o(1)$. We start by proving (7.1) in this case. In [18], it is proven that $|\mathcal{C}_1| \geq c\varepsilon V$ whp in this case, and the argument used there is based on isoperimetry together with Lemma 2.3 and suffices to prove the required $2\varepsilon V$ estimate in our setting as well, as we show now.

Let $\theta > 0$ be a small arbitrary constant. As before, fix the sprinkling probability $p_2 = \theta\varepsilon/m$ and take p_1 such that $p = p_c(1 + \varepsilon) = p_1 + (1 - p_1)p_2$ so that $p_1 = p_c(1 + (1 - \theta + o(1))\varepsilon)$. By Lemma 2.3, whp in G_{p_1} ,

$$2(1 - 2\theta)\varepsilon V \leq Z_{\geq k_0} \leq 2(1 + \theta)\varepsilon V,$$

for $k_0 = \varepsilon^{-2}(\varepsilon^3 V)^{1/4}$. As a result, there are at most $2(1 + \theta)\varepsilon V/k_0 = 2(1 + \theta)(\varepsilon^3 V)^{3/4}$ clusters of size at least k_0 . Denote these clusters by $(\mathcal{D}_i)_{i \in I}$, so that $|I| \leq 2(1 + \theta)(\varepsilon^3 V)^{3/4}$.

As before, we now perform sprinkling and add the edges of G_{p_2} . We bound the probability that after the sprinkling there is a partition of the clusters $(\mathcal{D}_i)_{i \in I}$ into two sets S, T both containing at least $\theta\varepsilon V$ vertices such that there is no path in G_{p_2} connecting them. If there is no such partition, then the largest component in $G_{p_1} \cup G_{p_2}$ has size at least $(2 - 3\theta)\varepsilon V$ and we conclude the proof. We follow [18, Proof of Proposition 2.5].

Since $|I| \leq 2(1 + \theta)(\varepsilon^3 V)^{3/4}$ the number of such partitions is at most $2^{2(1+\theta)(\varepsilon^3 V)^{3/4}}$. We bound the probability that given such a partition there is no p_2 -open path connecting them. By [18, Lemma 2.4], whenever $\Delta \geq 1$ satisfies

$$e^{-\Delta^2/2m} \leq \theta\varepsilon/2, \quad (7.17)$$

there is a collection of at least $\frac{1}{2}\theta\varepsilon m^{-2\Delta} V$ edge disjoint paths connecting S and T , each of length at most Δ . This is where the isoperimetric inequality on the hypercube is being used. Note that Δ needs to be large, in fact, we put $\Delta = m^{2/3}$ and use the fact that $\varepsilon \geq m^{-2}$ so that (7.17) holds. The probability that a path of length Δ has a p_2 -closed edge in it is $1 - p_2^\Delta$. Since the paths are disjoint, these events are independent, and we learn that the probability that they all have a p_2 -closed edge in them is at most

$$\left(1 - p_2^\Delta\right)^{\frac{1}{2}\theta\varepsilon m^{-2\Delta} V} \leq e^{-c p_2^\Delta \theta\varepsilon m^{-2\Delta} V} = e^{-c\theta^\Delta \varepsilon^\Delta m^{-3\Delta} V}. \quad (7.18)$$

Thus, the total probability that sprinkling fails is at most

$$2^{2(1+\theta)(\varepsilon^3 V)^{3/4}} e^{-c\theta^\Delta \varepsilon^\Delta m^{-3\Delta} V} = e^{-c2^{(1-o(1))m}}, \quad (7.19)$$

since $\varepsilon \geq m^{-2}$ (in fact, this argument works as long as $\varepsilon \geq e^{-cm^{1/3}}$). The proof of (7.1) when $\varepsilon \gg V^{-1/3}$ and $\varepsilon = o(1)$ is now completed.

The remaining bounds on $|\mathcal{C}_1|$, $\mathbb{E}|\mathcal{C}(0)|$ and $|\mathcal{C}_2|$ only rely on (7.1) and Lemma 2.3 and are performed exactly as in the conclusion of the proof of Theorem 1.3. This completes the proof of Theorem 1.1. \square

7.3. Proof of Theorem 1.4. Our expansion and girth assumption of the theorem allows us to deduce some crude yet sufficient bounds on $\mathbf{p}^t(\cdot, \cdot)$, namely, that there exists some constant $q > 0$ so that

$$\mathbf{p}^t(0, 0) \leq \begin{cases} V^{-q} & t \leq C \log V, \\ CV^{-1} & t \geq C \log V, \end{cases} \quad \text{and} \quad \mathbf{p}^t(x, y) \leq \begin{cases} (m-1)^{-t} & t \leq (c \log_{m-1} V)/2, \\ V^{-q} & t \geq (c \log_{m-1} V)/2. \end{cases}$$

Indeed, the second bound on $\mathbf{p}^t(0,0)$ comes from the classical fact that $T_{\text{mix}}(CV^{-1}) = O(\log V)$. See e.g. [5, below (19)]. The first bound on $\mathbf{p}^t(0,0)$ comes from the girth assumption. Indeed, the graph induced on the vertices of graph distance at most $\lfloor g/2 \rfloor$, where g is the girth, is a tree. Hence, in order for the walker to return to 0 at time t it must be at distance $t - \lfloor g/2 \rfloor$ from 0 and then take the unique path of length $\lfloor g/2 \rfloor$ to 0 so that q can be taken to be any number smaller than $c/2$. The bounds on $\mathbf{p}^t(x,y)$ are proved similarly.

We take $\alpha_V = C(\log V)^{-1}$ (which is at least $1/m$ by our assumption that $m \geq c \log V$) and prove that conditions (2) and (3) of Theorem 1.3 hold. Note that $m_0 = O(\log V)$. To show condition (2) we show that percolation with $p = (m-1)^{-1}(1 + \alpha_V / \log V)$ has $\mathbb{E}_p |\mathcal{C}(0)| \gg V^{1/3}$ so that $p_c \leq p$. To show this lower bound on $\mathbb{E}_p |\mathcal{C}(0)|$ in this regime of p it is possible to use a classical sprinkling argument. However, it is quicker to use [46, Theorem 4] and verify that

$$\varepsilon^{-1} r \sum_{t=1}^{2r} [(1 + \varepsilon)^{t \wedge r} - 1] \mathbf{p}^t(0,0) = o(1), \quad (7.20)$$

where $\varepsilon = \alpha_V / \log V$ and $r = \varepsilon^{-1} [\log(\varepsilon^3 V) - 3 \log \log(\varepsilon^3 V)]$. Theorem 4 of [46] then yields that $\mathbf{P}(|\mathcal{C}_1| \geq b \varepsilon V / (\log(\varepsilon^3 V))^3) = 1 - o(1)$ for some $b > 0$ which immediately gives a lower bound on $\mathbb{E} |\mathcal{C}(0)|$ since

$$\mathbb{E} |\mathcal{C}(0)| \geq V^{-1} \mathbb{E} |\mathcal{C}_1|^2 \geq (1 + o(1)) b^2 \varepsilon^2 V / (\log(\varepsilon^3 V))^6 \gg V^{1/3},$$

by our choice of ε . We use our bounds on $\mathbf{p}^t(0,0)$ above and sum (7.20) separately for $t \leq C \log V$ and $t \geq C \log V$. For $t \leq C \log V$ we bound $(1 + \varepsilon)^t - 1 = O(\varepsilon t)$ and use our first bound $\mathbf{p}^t(0,0) \leq V^{-q}$ to get

$$\varepsilon^{-1} r \sum_{t=1}^{C \log V} [(1 + \varepsilon)^{t \wedge r} - 1] \mathbf{p}^t(0,0) \leq r \sum_{t=1}^{C \log V} t V^{-q} = o(1).$$

When $t \geq C \log V$ we bound

$$(1 + \varepsilon)^{t \wedge r} - 1 \leq (1 + \varepsilon)^r = \varepsilon^3 V (\log \varepsilon^3 V)^{-3} = O(\varepsilon^3 V (\log V)^{-3}),$$

by our choice of ε . We use our second bound $\mathbf{p}^t(0,0) \leq CV^{-1}$ to bound

$$\varepsilon^{-1} r \sum_{t=C \log V}^{2r} [(1 + \varepsilon)^{t \wedge r} - 1] \mathbf{p}^t(0,0) = O(r^2 \varepsilon^2 (\log V)^{-3}) = o(1),$$

since $r \leq C(\log V)^2$. This concludes the verification of condition (2) of Theorem 1.3.

To verify condition (3) we need to prove the bound

$$\sum_{u,v} \sum_{t_1, t_2, t_3: t_1 + t_2 + t_3 \geq 3}^{C \log V} \mathbf{p}^{t_1}(x,u) \mathbf{p}^{t_2}(u,v) \mathbf{p}^{t_3}(v,y) = O((\log V)^{-2}). \quad (7.21)$$

We first handle the special case of $(t_1, t_2, t_3) = (1, 1, 1)$. An immediate calculation with Lemma 3.11 gives that (on any regular graph of degree m)

$$\sum_{u,v} \mathbf{p}^1(x,u) \mathbf{p}^1(u,v) \mathbf{p}^1(v,y) = O(1/m^2).$$

In all other cases of (t_1, t_2, t_3) we use our bound on $\mathbf{p}^{t_i}(x,y)$ for $i \in 1, 2, 3$ such that t_i is the largest of t_1, t_2, t_3 (which must be at least 2). We pull this bound out of the sum, and sum the other two terms over u and v to get a multiplicative contribution of precisely 1. The sum over (t_1, t_2, t_3) such that $3 \leq t_1 + t_2 + t_3 < 15$ is bounded by $C(\log V)^{-2}$ since the number of such triplets is bounded, and each contributes at most $C(\log V)^{-2}$ because one of the t_i 's is at least 2, so that our bounds on $\mathbf{p}^t(x,y)$ guarantee that for this t_i we have $\mathbf{p}^{t_i}(\cdot, \cdot) \leq O(1/m^2) \leq O(1/(\log V)^2)$ by the assumption that $m \geq c \log V$. Similarly, the sum over triplets (t_1, t_2, t_3) such that $t_1 + t_2 + t_3 \geq 15$ and $t_i \leq m_0$ is also bounded by $C(\log V)^{-2}$ since the number of such triplets is at most $C(\log V)^3$, and each contributes at

most $C(\log V)^{-5}$ because at least one of the t_i 's is at least 5 and for this t_i we have $\mathbf{p}^{t_i}(\cdot, \cdot) \leq C(\log V)^{-5}$ again by our assumption that $m \geq c \log V$. This concludes our verification of conditions (2) and (3) of Theorem 1.3 and concludes our proof. \square

8. OPEN PROBLEMS

- (1) In this paper we prove a law of large numbers for $|\mathcal{C}_1|$ above the critical window for percolation on the hypercube. Show that $|\mathcal{C}_1|$ satisfies a central limit theorem in this regime. In $G(n, p)$ this and much more was established by Pittel and Wormald [51].
- (2) Show that $|\mathcal{C}_2| = (2+o(1))\varepsilon^{-2} \log(\varepsilon^3 2^m)$ when $p = p_c(1+\varepsilon)$ and that $|\mathcal{C}_1| = (2+o(1))\varepsilon^{-2} \log(\varepsilon^3 2^m)$ when $p = p_c(1-\varepsilon)$ for $\varepsilon \gg V^{-1/3}$ and $\varepsilon = o(1)$. This is the content of [18, Conjectures 3.1 and 3.3]. In [15] this is proved for $\varepsilon \geq 60(\log n)^3/n$ in the supercritical regime, and for $\varepsilon \geq (\log n)^2/(n^{1/2} \log \log n)$ in the subcritical regime. In $G(n, p)$ these results are proved in [51] and [38, Theorem 5.6].
- (3) Show that $(|\mathcal{C}_j|2^{-2m/3})_{j \geq 1}$ converges in distribution when $p = p_c(1+t2^{-m/3})$ and $t \in \mathbb{R}$ is fixed and identify the limit distribution. Up to a time change, this should be the limiting distribution of $(|\mathcal{C}_j|n^{-2/3})_{j \geq 1}$ in $G(n, p)$ with $p = (1+tn^{-1/3})/n$ identified by Aldous [4].
- (4) Consider percolation on the nearest-neighbor torus \mathbb{Z}_n^d where d is a large fixed constant and $n \rightarrow \infty$ with $p = p_c(1+\varepsilon)$ such that $\varepsilon \gg n^{-d/3}$ and $\varepsilon = o(1)$. Show that $|\mathcal{C}_1|/(\varepsilon n^d)$ converges to a constant. Does this constant equal the limit as $\varepsilon \downarrow 0$ of $\varepsilon^{-1}\theta_{\mathbb{Z}^d}(p_c(1+\varepsilon))$? Here $\theta_{\mathbb{Z}^d}(p)$ denotes the probability that the cluster of the origin is infinite at p -bond percolation on the infinite lattice \mathbb{Z}^d . The techniques of this paper are not sufficient to show this mainly because condition (2) of Theorem 1.3 does not hold in \mathbb{Z}_n^d (in fact, it is easy to see that $p_c - (2d-1)^{-1} \geq c > 0$ for some positive constant $c = c(d)$ — this is always the case when our underlying transitive graph has constant degree and short cycles). The critical regime of this graph is well understood by the works [16, 17, 29, 30].
- (5) Show that the finite triangle condition (1.5) holds on any family of expander graphs.
- (6) Let $\delta > 0$ be a fixed constant and consider the giant component \mathcal{C}_1 obtained by performing percolation on the hypercube with $p = (1+\delta)/m$. Show that whp the mixing time of the simple random walk on \mathcal{C}_1 is polynomial in m . Is this mixing time of order m^2 ? This is what one expects by the analogous question on $G(n, p)$, see [10, 26]. Further analogy with the near-critical $G(n, p)$ (see [22]) suggests that whp the mixing time on \mathcal{C}_1 when $p = p_c(1+\varepsilon)$ with the usual condition that $\varepsilon \gg 2^{-m/3}$ and $\varepsilon = o(1)$ is of order $\varepsilon^{-3} \log(\varepsilon^3 2^m)$.

APPENDIX A. ASYMPTOTICS OF THE SUPER-CRITICAL CLUSTER TAIL

Our goal in this section is to prove Theorem 2.2. In [16], Theorem 2.2 is proved without the precise constant 2. Here we sharpen this proof to get this constant. We assume that G is a general transitive graph having degree m and volume V satisfying the finite triangle condition (1.5). In order to stay close to the notation in [16], we define

$$\nabla_p^{\max} = \sup_{x \neq y} \nabla_p(x, y),$$

and

$$\tau_p(x) = \mathbf{P}_p(0 \longleftrightarrow x). \tag{A.1}$$

Proposition A.1 (Upper bound on the cluster tail). *Let G be a finite transitive graph of degree m on V vertices such that the finite triangle condition (1.5) holds and put $p = p_c(1 + \varepsilon)$ where $\varepsilon = o(1)$ and $\varepsilon \gg V^{-1/3}$. Then, for every $k = k_\varepsilon$ satisfying $k_\varepsilon \geq \varepsilon^{-2}$,*

$$\mathbf{P}_p(|\mathcal{C}(0)| \geq k) \leq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3 V)^{-1} + (\varepsilon^2 k)^{-1/4} + \alpha_V)). \quad (\text{A.2})$$

Proposition A.2 (Lower bound on the cluster tail). *Let G be a finite transitive graph of degree m on V vertices such that the finite triangle condition (1.5) holds and put $p = p_c(1 + \varepsilon)$ where $\varepsilon = o(1)$ and $\varepsilon \gg V^{-1/3}$. Then, for every $\alpha \in (0, 1/3)$, there exists a $c = c(\alpha) > 0$ such that*

$$\mathbf{P}_p\left(|\mathcal{C}(0)| \geq \varepsilon^{-2}(\varepsilon^3 V)^\alpha\right) \geq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3 V)^{-c} + \alpha_V)). \quad (\text{A.3})$$

Remark. The above propositions apply also to infinite transitive graphs (where $(\varepsilon^3 V)^{-c}$ is replaced by 0), assuming that (1.5) holds with $\chi(p)^3/V$ replaced by 0.

Proof of Theorem 2.2. Follows immediately from the above propositions. \square

A.1. Differential inequalities. We follow [16, Section 5]. For $p, \gamma \in [0, 1]$, we define the *magnetization* by

$$M(p, \gamma) = \sum_{k=1}^V [1 - (1 - \gamma)^k] \mathbf{P}_p(|\mathcal{C}(0)| = k). \quad (\text{A.4})$$

For fixed p , the function $\gamma \mapsto M(p, \gamma)$ is strictly increasing, with $M(p, 0) = 0$ and $M(p, 1) = 1$. When we color all vertices independently *green* with probability γ , and we let \mathcal{G} denote the set of green vertices, then (A.4) has the appealing probabilistic interpretation of

$$M(p, \gamma) = \mathbf{P}_{p, \gamma}(0 \longleftrightarrow \mathcal{G}), \quad (\text{A.5})$$

where $\mathbf{P}_{p, \gamma}$ is the probability measure of the joint bond and site percolation model, where bonds and sites have an independent status. This representation is important for the derivation of useful differential inequalities involving the magnetization.

Lemma A.3 (Differential inequalities for the magnetization). *Let G be a finite transitive graph on V vertices and degree m . Then at any $p, \gamma \in (0, 1)$*

$$(1 - p) \frac{\partial M}{\partial p} \leq m(1 - \gamma) M \frac{\partial M}{\partial \gamma}, \quad (\text{A.6})$$

$$M \leq \gamma \frac{\partial M}{\partial \gamma} + \left[\frac{1}{2} m p M^2 + \gamma M \right] + \left[\frac{1}{2} m p M + \gamma \right] p \frac{\partial M}{\partial p}, \quad (\text{A.7})$$

and

$$M \geq m p \left[\gamma + (1 - \gamma) \frac{1}{2} m(m - 1) p^2 \alpha(p) M^2 \right] \frac{\partial M}{\partial \gamma}, \quad (\text{A.8})$$

where

$$\alpha(p) = (1 - 2p)^2 - (1 + m p + 2(m p)^2) \nabla_p^{\max} - m p M - (m p)^2 M^2. \quad (\text{A.9})$$

The inequality (A.6) is proved in [1], where it was used to prove the sharpness of the percolation phase transition on \mathbb{Z}^d , and was first stated in the context of finite graphs in [16, (5.14)]. The differential inequality in (A.7) is an adaptation of another differential inequality proved and used in [1], which is improved here in order to obtain sharp constants in our bounds. The bound in (A.8) is an adaptation of [16, (5.16)], which was used there in order to prove an upper bound on $M(p, \gamma)$. Again, the inequality is adapted in order to obtain the optimal constants. We will first use Lemma A.3 to obtain Propositions A.1 and A.2.

A.2. The magnetization for subcritical p . We take $p = p_c(1 - \varepsilon)$ with $\varepsilon = o(1)$ and $\varepsilon^3 V \gg 1$, and we take $\gamma = o(1)$. Then, [16, Lemma 5.3] shows that $M(p, \gamma) = O(\sqrt{\gamma})$. The main aim of this section is to improve upon this bound, using the improved differential inequality in (A.8).

We have that $M(p, \gamma) = O(\sqrt{\gamma})$ and $\chi(p) = O(1/\varepsilon)$ by [16, Theorem 1.5]. Further more, assumption (1.5) gives that $\nabla_p^{\max} = O(\alpha_V + (\varepsilon^3 V)^{-1})$ and [16, (1.30)] then implies that $mp \leq 1 + O(\alpha_V)$. Putting all this into (A.9) yields

$$\alpha(p) \geq 1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V). \quad (\text{A.10})$$

Substituting (A.10) into (A.8) in turn gives that

$$M \geq (1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V)) \left[\gamma + \frac{1}{2} M^2 \right] \frac{\partial M}{\partial \gamma}. \quad (\text{A.11})$$

We now use this to prove the following lemma:

Lemma A.4 (Upper bound on the slightly subcritical magnetization). *Let G be a finite transitive graph of degree m on V vertices such that the finite triangle condition (1.5) holds. Let $\gamma = o(1)$ and put $p = p_c(1 - \varepsilon)$ with $\varepsilon = o(1)$ and $\varepsilon^3 V \gg 1$. Then,*

$$M(p, \gamma) \leq \sqrt{2\gamma} (1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V)). \quad (\text{A.12})$$

A similar bound as in Lemma A.4 was proved in [16, Lemma 5.3], whose proof we adapt here, with $\sqrt{2\gamma}$ replaced with $\sqrt{12\gamma}$, and a less precise error bound. The precise constant $\sqrt{2}$ is important for us here as it relates to the constant 2 for the $2\varepsilon(1 + o(1))$ survival probability.

Proof. We note that (A.11) implies that

$$M \geq \frac{B}{2} M^2 \frac{\partial M}{\partial \gamma}, \quad (\text{A.13})$$

where we abbreviate $B = 1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V)$. Therefore,

$$\frac{\partial[M^2]}{\partial \gamma} \leq 4/B. \quad (\text{A.14})$$

Integrating between 0 and γ , and using that $M(p, 0) = 0$ yields that

$$M^2 \leq 4\gamma/B, \quad (\text{A.15})$$

so that $M \leq \sqrt{\gamma}(2/\sqrt{B})$. Now, when we have this inequality, we can further bound

$$\gamma \geq \frac{B}{4} M^2, \quad (\text{A.16})$$

so that by (A.11) we get

$$M \geq B[1/2 + B/4] M^2 \frac{\partial M}{\partial \gamma}. \quad (\text{A.17})$$

Performing the same integration steps, we arrive at

$$M^2 \leq \frac{2}{B/2 + B^2/4} \gamma. \quad (\text{A.18})$$

Therefore, the constant has become a little better (recall that B is close to 1). Iterating these steps yields that, for every $k \geq 1$,

$$M^2 \leq \frac{2}{\sum_{l=1}^k (B/2)^l} \gamma. \quad (\text{A.19})$$

We prove (A.19) by induction on k , the initialization for $k = 1, 2$ having been proved above. To advance the induction hypothesis, suppose that (A.19) holds for $k \geq 1$. Define

$$A_k = \sum_{l=1}^k (B/2)^l, \quad (\text{A.20})$$

so that (A.19) is equivalent to $M^2 \leq 2\gamma/A_k$. In turn, this yields that $\gamma \geq A_k M^2/2$, so that

$$M \geq B \left[A_k/2 + 1/2 \right] M^2 \frac{\partial M}{\partial \gamma}, \quad (\text{A.21})$$

which in turn yields that

$$M^2 \leq \frac{2}{B[1 + A_k]/2} \gamma. \quad (\text{A.22})$$

Note that

$$B[1 + A_k]/2 = A_{k+1}, \quad (\text{A.23})$$

which advances the induction. By (A.19), we obtain that

$$M^2 \leq \frac{2}{\sum_{l=1}^{\infty} (B/2)^j} \gamma = 2[2 - B]\gamma/B. \quad (\text{A.24})$$

Finally, the fact that

$$[2 - B]/B = 1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V) \quad (\text{A.25})$$

completes the proof. \square

A.3. The magnetization for supercritical p . In this section, we use *extrapolation inequalities* to obtain a bound on the supercritical magnetization from the subcritical one derived in Lemma A.4. Our precise result is the following:

Lemma A.5 (Upper bound on the slightly supercritical magnetization). *Let G be a finite transitive graph of degree m on V vertices such that the finite triangle condition (1.5) holds and put $p = p_c(1 + \varepsilon)$ where $\varepsilon = o(1)$ and $\varepsilon \gg V^{-1/3}$. Then for any $c \in (0, 1/3)$,*

$$M(p, \gamma) \leq \left(\varepsilon + \sqrt{2\gamma + \varepsilon^2} \right) \left(1 + O(\varepsilon + \sqrt{\gamma} + (\varepsilon^3 V)^{-c} + \alpha_V) \right). \quad (\text{A.26})$$

Proof. We follow the proof in [16, Section 5.3], paying special attention to the constants and error terms. Indeed, we use (A.6) and the chain rule to deduce that, with $A = (1 - 2p_c)^{-1}$, and $\tilde{M}(p, h) = M(p, 1 - e^{-h})$,

$$\frac{\partial \tilde{M}}{\partial p} \leq mA\tilde{M} \frac{\partial \tilde{M}}{\partial h}. \quad (\text{A.27})$$

Take $P_1 = (p_c(1 + \varepsilon), h)$ and write $m_1 = \tilde{M}(P_1)$. Further, take $\eta = \varepsilon(\varepsilon^3 V)^{-c}$ for some $c \in (0, 1/3)$, so that $\eta = o(\varepsilon)$ and $\eta^3 V \rightarrow \infty$, and take $P_2 = (p_c(1 - \eta), Am_1 \varepsilon')$, where

$$\varepsilon' = \varepsilon + \eta + \frac{h}{Am_1}. \quad (\text{A.28})$$

Then, with $m_2 = \tilde{M}(P_2)$, we have that $m_2 \geq m_1$ (see e.g., [16, (5.46)]). Therefore, by Lemma A.4 and again writing $B = 1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V)$ with $\gamma = 1 - e^{-h}$,

$$\begin{aligned} M(p, 1 - e^{-h}) &= m_1 \leq m_2 \leq \sqrt{2B(1 - e^{-Am_1 \varepsilon'})} \\ &= (1 + O(m_1 \varepsilon')) \sqrt{2ABm_1 \varepsilon'} \\ &= (1 + O(m_1 \varepsilon)) \sqrt{2ABm_1(\varepsilon + \eta) + 2Bh} \\ &= (1 + O(\varepsilon + (\varepsilon^3 V)^{-c})) \sqrt{2ABm_1 \varepsilon + 2Bh}, \end{aligned} \quad (\text{A.29})$$

where in the last inequality we use that $\eta = \varepsilon(\varepsilon^3 V)^{-c} \ll \varepsilon$ and $m_1 \leq 1$. The inequality

$$m_1 \leq \sqrt{2ABm_1 \varepsilon + 2Bh}$$

has roots

$$m^\pm = AB\varepsilon \pm \sqrt{2Bh + (AB\varepsilon)^2}. \quad (\text{A.30})$$

Since $m_1 \geq 0$ and $m_+ \geq 0$ while $m_- \leq 0$, we deduce that

$$M(p_c + \varepsilon/m, 1 - e^{-h}) = m_1 \leq (1 + O(\varepsilon + (\varepsilon^3 V)^{-c}))(AB\varepsilon + \sqrt{2Bh + (AB\varepsilon)^2}). \quad (\text{A.31})$$

We have that $\gamma = 1 - e^{-h} = h(1 + O(h))$ and $A = 1 + O(\alpha_V)$ (by [16, (1.30)]) and $B = 1 + O(\sqrt{\gamma} + (\varepsilon^3 V)^{-1} + \alpha_V)$. Putting all this together in the last inequality completes the proof. \square

Proof of Proposition A.1. We note that, for any $l \geq k \geq 1$ and $a > 0$,

$$1 - (1 - a/k)^l \geq 1 - e^{-a}. \quad (\text{A.32})$$

Therefore, by (A.4),

$$\mathbf{P}_p(|\mathcal{C}(0)| \geq k) \leq [1 - e^{-a}]^{-1} M(p, a/k). \quad (\text{A.33})$$

Recall that $k \gg \varepsilon^{-2}$ and take $a = (\varepsilon^2 k)^{1/2}$ so that $a/k = \varepsilon^2 (\varepsilon^2 k)^{-1/2} = o(\varepsilon^2)$. We note that for $\gamma = \varepsilon^2 (\varepsilon^2 k)^{-1/2}$, (A.26) reduces to

$$M(p, \gamma) \leq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3 V)^{-1} + (\varepsilon^2 k)^{-1/4} + \alpha_V)). \quad (\text{A.34})$$

Then, by (A.34) and the fact that $1 - e^{-a} = 1 + o((\varepsilon^2 k)^{-1/4})$,

$$M(p, a/k) \leq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3 V)^{-1} + (\varepsilon^2 k)^{-1/4} + \alpha_V)). \quad (\text{A.35})$$

This completes the proof of Proposition A.1. \square

A.4. Lower bound on tail probabilities. In the remainder of this section, we shall prove Proposition A.2. Throughout this proof, we will take $p = p_c(1 + \varepsilon)$.

We shall assume that with $k_0 = \varepsilon^{-2}(\varepsilon^3 V)^\alpha \gg \varepsilon^{-2}$ and $\alpha \in (0, 1/3)$, there exists $b_{10} = b_{10}(\alpha)$ such that

$$\mathbf{P}_p(|\mathcal{C}(v)| \geq \varepsilon^{-2}(\varepsilon^3 V)^\alpha) \geq b_{10}\varepsilon. \quad (\text{A.36})$$

The bound in (A.36) is proved for finite graphs in [16, Theorem 1.6(i)] and in [9], in conjunction with [28], on infinite lattices satisfying the triangle condition. The proof of (A.36) is similar to the argument we shall give for the improved bound, and shall be omitted here. In turn, (A.36) implies that, for $\gamma = 1/k_0 = \varepsilon^2(\varepsilon^3 V)^{-\alpha} = o(\varepsilon^2)$, there exists a constant \tilde{b}_{10} such that

$$M(p, \gamma) \geq [1 - [1 - \gamma]^{k_0}] \mathbf{P}_p(|\mathcal{C}(v)| \geq k_0) \geq \tilde{b}_{10}\varepsilon. \quad (\text{A.37})$$

Equation (A.37) will be an essential ingredient in our proof. We start by proving the following lemma:

Lemma A.6 (Lower bound on the magnetization). *Let G be a finite transitive graph of degree m on V vertices such that the finite triangle condition (1.5) holds and put $p = p_c(1 + \varepsilon)$ where $\varepsilon = o(1)$ and $\varepsilon \gg V^{-1/3}$. Then, for $\gamma = \varepsilon^2(\varepsilon^3 V)^{-\alpha}$ with $\alpha \in (0, 1/3)$ and any $c < 1$,*

$$M(p, \gamma) \geq 2\varepsilon[1 + O(\varepsilon + (\varepsilon^3 V)^{-c} + \alpha_V)]. \quad (\text{A.38})$$

Proof. Throughout the proof, we fix $\alpha \in (0, 1/3)$. We recall the differential inequality (A.7)

$$M \leq \gamma \frac{\partial M}{\partial \gamma} + \left[\frac{1}{2} mpM^2 + \gamma M \right] + \left[\frac{1}{2} mpM + \gamma \right] p \frac{\partial M}{\partial p}. \quad (\text{A.39})$$

By (A.37), and the fact that $\gamma \mapsto M(p, \gamma)$ is increasing, for any $\gamma = \varepsilon^2(\varepsilon^3 V)^{-\alpha}$ we have that $\gamma = O(M\varepsilon)$. Further, $mp \leq 1 + O(\varepsilon + \alpha_V)$, so that, for some $A > 1$ with $A = 1 + O(\varepsilon + \alpha_V)$ we obtain

$$M \leq \gamma \frac{\partial M}{\partial \gamma} + \frac{A}{2} M^2 + \frac{A}{2} Mp \frac{\partial M}{\partial p}. \quad (\text{A.40})$$

We rewrite (A.40) as

$$0 \leq \frac{1}{M} \frac{\partial M}{\partial \gamma} + \frac{1}{\gamma} \frac{\partial}{\partial p} \left[\frac{A}{2} pM - p \right], \quad (\text{A.41})$$

and integrate for $\gamma \in [\gamma_0, \gamma_1]$ and $p \in [p_0, p_1]$, where $\gamma_0 = (\delta\varepsilon)^2(\delta^3\varepsilon^3V)^{-\alpha}$. We note that (A.37) holds for $p_0 = p_c(1 + \varepsilon\delta)$ for any $\delta = o(1)$ and $\gamma = \gamma_0$. We further take

$$p_0 = p_c(1 + \delta\varepsilon), \quad p_1 = p_c(1 + \varepsilon), \quad \gamma_1 = e^{(\log(1/\delta))^a} \gamma_0, \quad (\text{A.42})$$

where $a > 1$ is chosen below.

Then, as in [27, (5.57) and the argument below it], by the fact that $p \mapsto M(p, \gamma)$ and $\gamma \mapsto M(p, \gamma)$ are non-decreasing,

$$0 \leq (p_1 - p_0) \log \frac{M(p_1, \gamma_1)}{M(p_0, \gamma_0)} + \log(\gamma_1/\gamma_0) \left[\frac{A}{2} p_1 M(p_1, \gamma_1) - (p_1 - p_0) \right]. \quad (\text{A.43})$$

Now,

$$\log(\gamma_1/\gamma_0) = (\log(1/\delta))^a, \quad (\text{A.44})$$

while, by Lemma A.5 and (A.37),

$$M(p_1, \gamma_1) \leq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3V)^{-1})), \quad M(p_0, \gamma_0) \geq \tilde{b}_{10}\delta\varepsilon, \quad (\text{A.45})$$

so that, for $\delta > 0$ sufficiently small,

$$\log \frac{M(p_1, \gamma_1)}{M(p_0, \gamma_0)} \leq \log(2\varepsilon/(\tilde{b}_{10}\delta\varepsilon)) \leq 2\log(1/\delta). \quad (\text{A.46})$$

Dividing (A.43) through by $(\log(1/\delta))^a$, we arrive at

$$\frac{A}{2} p_1 M(p_1, \gamma_1) \geq p_c(1 - \delta)\varepsilon \left[1 - 2(\log(1/\delta))^{1-a} \right]. \quad (\text{A.47})$$

Recalling that $p_1 = p_c(1 + \varepsilon)$ and that $a > 1$, as well as the fact that $A = 1 + O(\varepsilon + \alpha_V)$, this yields

$$M(p, \gamma_1) \geq 2\varepsilon[1 + O(\varepsilon + (\log(1/\delta))^{1-a} + \alpha_V)]. \quad (\text{A.48})$$

Finally, note that

$$\begin{aligned} \gamma_1 &= e^{(\log(1/\delta))^a} \gamma_0 = e^{(\log(1/\delta))^a} (\delta\varepsilon)^2 (\delta^3\varepsilon^3V)^{-\alpha} \\ &= \varepsilon^2 (\varepsilon^3V)^{-\alpha} (e^{(\log(1/\delta))^a} \delta^{2-3\alpha}) \geq \varepsilon^2 (\varepsilon^3V)^{-\alpha}, \end{aligned} \quad (\text{A.49})$$

when we take $\delta = e^{-(\varepsilon^3V)^{1/a}}$ for any $a > 1$. Indeed, then $e^{(\log(1/\delta))^a} \delta^{2-3\alpha} \rightarrow \infty$ as $\delta \rightarrow 0$. Since $\gamma \mapsto M(p, \gamma)$ is increasing, this implies that

$$M(p, \gamma) \geq M(p, \gamma_1) \geq 2\varepsilon[1 + O(\varepsilon + (\log(1/\delta))^{1-a} + \alpha_V)] = 2\varepsilon[1 + O(\varepsilon + (\varepsilon^3V)^{1/a-1} + \alpha_V)]. \quad (\text{A.50})$$

Denoting $c = 1 - 1/a$, this proves the claim. \square

Proof of Proposition A.2. We use [16, (6.5) in Lemma 6.1], which states that, for any $0 \leq \gamma_0, \gamma_1 \leq 1$,

$$\mathbf{P}_p(|\mathcal{C}(0)| \geq k) \geq M(p, \gamma_1) - \frac{\gamma_1}{\gamma_0} e^{\gamma_0 k} M(p, \gamma_0). \quad (\text{A.51})$$

Now we take $\gamma_1 = \varepsilon^2 (\varepsilon^3V)^{-\alpha'}$ with $\alpha' \in (0, 1/3)$ taken as in Lemma A.6, $\gamma_0 = \varepsilon^2 (\varepsilon^3V)^{-\alpha}$ with $\alpha < \alpha'$, and $k = 1/\gamma_0$. Then $e^{\gamma_0 k} = e$, while, by Lemma A.5 and the fact that $\gamma_0 = o(\varepsilon^2)$, we obtain that

$$M(p, \gamma_0) \leq 2\varepsilon(1 + o(1)). \quad (\text{A.52})$$

Therefore, by Lemma A.6 and (A.51), taking $c = 1/2$ in Lemma A.6,

$$\mathbf{P}_p(|\mathcal{C}(0)| \geq k) \geq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3V)^{-1/2} + \alpha_V)) - (\varepsilon^3V)^{\alpha' - \alpha} O(\varepsilon). \quad (\text{A.53})$$

We obtain that

$$\mathbf{P}_p(|\mathcal{C}(0)| \geq \varepsilon^{-2} (\varepsilon^3V)^\alpha) \geq 2\varepsilon(1 + O(\varepsilon + (\varepsilon^3V)^{-1/2} + (\varepsilon^3V)^{\alpha - \alpha'} + \alpha_V)). \quad (\text{A.54})$$

This proves the claim in Proposition A.2 with $c = \alpha - \alpha' \in (0, 1/3)$. \square

A.5. Derivation of (A.8). We follow the proof in [16, Appendix A.2] as closely as possible, deviating in one essential inequality. Indeed, in [16, (A.23-A.32)], it is proved that

$$M(p, \gamma) \geq pm \frac{\partial M}{\partial \gamma}(p, \gamma) \mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G}) - X_2 - X_3, \quad (\text{A.55})$$

where X_2 and X_3 are defined in [16, A.32] and the event $0 \Leftrightarrow \mathcal{G}$ means that there are $x, y \in \mathcal{G}$ with $x \neq y$ such that $0 \leftrightarrow x$ and $0 \leftrightarrow y$ disjointly. We copy the bounds on X_2 and X_3 in [16, (A.46)] and [16, (A.53)] respectively, which prove that

$$X_2 \leq p^2 m M^2(p, \gamma) \frac{\partial M}{\partial \gamma}(p, \gamma), \quad X_3 \leq \nabla_p^{\max} pm M^2(p, \gamma) \frac{\partial M}{\partial \gamma}(p, \gamma), \quad (\text{A.56})$$

and we improve upon the lower bound on $\mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G})$ only. Our precise results is contained in the following lemma:

Lemma A.7 (Improved lower bound on the double connection). *For all $p, \gamma \in [0, 1]$,*

$$\mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G}) \geq \gamma + (1 - \gamma) \frac{1}{2} m(m - 1) p^2 \alpha(p) M^2(p, \gamma), \quad (\text{A.57})$$

where

$$\alpha(p) = (1 - 2p)^2 - (1 + mp + 2(mp)^2) \nabla_p^{\max} - mpM(p, \gamma) - (mp)^2 M(p, \gamma)^2.$$

Proof. Note that if $0 \in \mathcal{G}$, then $0 \Leftrightarrow \mathcal{G}$ occurs. Therefore, we obtain

$$\mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G}) = \gamma + (1 - \gamma) \mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G} \mid 0 \notin \mathcal{G}). \quad (\text{A.58})$$

Thus, we are left to obtain a lower bound on $\mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G} \mid 0 \notin \mathcal{G})$. For this, we follow the original argument in [16, Section A.2], adapting it when necessary.

For a directed bond $b = (x, y)$, we write $\underline{b} = x$ and $\bar{b} = y$ for its top and bottom. Let e, f be two distinct bonds with $\underline{e} = \underline{f} = 0$, and let $E_{e, f}$ be the event that the bonds e and f are occupied, and that in the reduced graph $G^- = (V^-, E^-)$ obtained by removing the bonds e and f , the following three events occur: $\bar{e} \longleftrightarrow \mathcal{G}$, $\bar{f} \longleftrightarrow \mathcal{G}$, and $\mathcal{C}(\bar{e}) \cap \mathcal{C}(\bar{f}) = \emptyset$.

Let $\mathbf{P}_{p, \gamma}^-$ denote the joint bond/vertex measure on G^- . We note that the event $\{0 \Leftrightarrow \mathcal{G}\}$ contains the event $\cup_{e, f} E_{e, f}$, where the (non-disjoint) union is over unordered pairs of bonds e, f incident to the origin. Then, by Bonferroni's inequality and since $E_{e, f}$ is independent of $0 \notin \mathcal{G}$, we get

$$\begin{aligned} \mathbf{P}_{p, \gamma}(0 \Leftrightarrow \mathcal{G} \mid 0 \notin \mathcal{G}) &\geq \mathbf{P}_{p, \gamma}(\cup_{e, f} E_{e, f} \mid 0 \notin \mathcal{G}) \geq \sum_{\{e, f\}} \mathbf{P}_{p, \gamma}(E_{e, f}) - Y_1 \\ &= p^2 \sum_{e, f} \mathbf{P}_{p, \gamma}^-(\bar{e} \longleftrightarrow \mathcal{G}, \bar{f} \longleftrightarrow \mathcal{G}, \mathcal{C}(\bar{e}) \cap \mathcal{C}(\bar{f}) = \emptyset) - Y_1, \end{aligned} \quad (\text{A.59})$$

where

$$Y_1 = \frac{1}{2} \sum_{\{e_1, f_1\} \neq \{e_2, f_2\}} \mathbf{P}_{p, \gamma}(E_{e_1, f_1} \cap E_{e_2, f_2} \mid 0 \notin \mathcal{G}). \quad (\text{A.60})$$

We first bound Y_1 . For this, we note that there are two contributions to Y_1 , depending on the number of distinct elements in $\{e_1, f_1, e_2, f_2\}$, which can be 3 or 4, and whose contributions we denote by $Y_{1,3}$ and $Y_{1,4}$, respectively.

We start by bounding $Y_{1,3}$. The number of pairs of pairs of edges $\{e_1, f_1\} \neq \{e_2, f_2\}$ such that $|\{e_1, f_1, e_2, f_2\}| = 3$ is $m(m - 1)(m - 2)$. For such a pair, let x_1, x_2, x_3 denote the distinct elements of $\{\bar{e}_1, \bar{f}_1, \bar{e}_2, \bar{f}_2\}$ such that x_1 corresponds to the end of the edge that appears twice in $\{e_1, f_1, e_2, f_2\}$. If $E_{e_1, f_1} \cap E_{e_2, f_2}$ occurs, then either

$$\{(0, x_1) \text{ occ.}\} \circ \{(0, x_2) \text{ occ.}\} \circ \{(0, x_3) \text{ occ.}\} \circ \{x_1 \longleftrightarrow \mathcal{G}\} \circ \{x_2 \longleftrightarrow \mathcal{G}\} \circ \{x_3 \longleftrightarrow \mathcal{G}\}$$

occurs, or there exists a z such that

$$\begin{aligned} & \{(0, x_1) \text{ occ.}\} \circ \{(0, x_2) \text{ occ.}\} \circ \{(0, x_3) \text{ occ.}\} \circ \{x_1 \longleftrightarrow \mathcal{G}\} \\ & \circ \{x_2 \longleftrightarrow z\} \circ \{x_3 \longleftrightarrow z\} \circ \{z \longleftrightarrow \mathcal{G}\} \end{aligned}$$

occurs. Therefore,

$$Y_{1,3} \leq (1-\gamma) \frac{1}{2} m(m-1)(m-2)p^3 M(p, \gamma)^2 [M(p, \gamma) + \nabla_p^{\max}], \quad (\text{A.61})$$

where we bounded

$$\sum_z \mathbf{P}_p(x_2 \longleftrightarrow z) \mathbf{P}_p(x_3 \longleftrightarrow z) \leq \nabla_p^{\max},$$

which is wasteful, but sufficient for our purposes.

For $Y_{1,4}$, we sum over $\{e_1, f_1\} \neq \{e_2, f_2\}$ with the constraint that all these edges are distinct. The number of such pairs of pairs is $m(m-1)(m-2)(m-3)/4$. Then, a similar computation as for $Y_{1,3}$ yields that

$$Y_{1,4} \leq (1-\gamma) \frac{1}{8} m(m-1)(m-2)(m-3)p^4 M(p, \gamma)^2 [M(p, \gamma)^2 + 8\nabla_p^{\max}]. \quad (\text{A.62})$$

We continue to bound the sum over $\{e, f\}$ in (A.59) from below. Let

$$W = W_{e,f} = \{\bar{e} \longleftrightarrow \mathcal{G}, \bar{f} \longleftrightarrow \mathcal{G}, \mathcal{C}(\bar{e}) \cap \mathcal{C}(\bar{f}) = \emptyset\}, \quad (\text{A.63})$$

denote the event whose probability appears on the right side of (A.59). Conditioning on the set $\mathcal{C}(\bar{e}) = A \subset V^-$, we see that

$$\mathbf{P}_{p,\gamma}^-(W) = \sum_{A: \bar{f} \notin A} \mathbf{P}_{p,\gamma}^-(\mathcal{C}(\bar{e}) = A, \bar{e} \longleftrightarrow \mathcal{G}, \bar{f} \longleftrightarrow \mathcal{G}, \mathcal{C}(\bar{e}) \cap \mathcal{C}(\bar{f}) = \emptyset). \quad (\text{A.64})$$

This can be rewritten as

$$\mathbf{P}_{p,\gamma}^-(W) = \sum_{A: \bar{f} \notin A} \mathbf{P}_{p,\gamma}^-(\mathcal{C}(\bar{e}) = A, \bar{e} \longleftrightarrow \mathcal{G}, \bar{f} \longleftrightarrow \mathcal{G} \text{ in } V^- \setminus A), \quad (\text{A.65})$$

where $\{\bar{f} \longleftrightarrow \mathcal{G} \text{ in } V^- \setminus A\}$ is the event that there exists $x \in \mathcal{G}$ such that $\bar{f} \longleftrightarrow x$ in $V^- \setminus A$. The intersection of the first two events on the right hand side of (A.65) is independent of the third event, and hence

$$\mathbf{P}_{p,\gamma}^-(W) = \sum_{A: \bar{e} \notin A} \mathbf{P}_{p,\gamma}^-(\mathcal{C}(\bar{e}) = A, \bar{e} \longleftrightarrow \mathcal{G}) \mathbf{P}_{p,\gamma}^-(\bar{f} \longleftrightarrow \mathcal{G} \text{ in } V^- \setminus A). \quad (\text{A.66})$$

Let $M^-(x) = \mathbf{P}_{p,\gamma}^-(x \longleftrightarrow \mathcal{G})$, for $x \in V^-$. Then, by the BK inequality and the fact that the two-point function on G^- is bounded above by the two-point function on G ,

$$\begin{aligned} \mathbf{P}_{p,\gamma}^-(\bar{f} \longleftrightarrow \mathcal{G} \text{ in } V^- \setminus A) &= M^-(\bar{f}) - \mathbf{P}_{p,\gamma}^-(\bar{f} \longleftrightarrow \mathcal{G} \text{ only on } A) \\ &\geq M^-(\bar{f}) - \sum_{y \in A} \tau_p(\bar{f}, y) M^-(y). \end{aligned} \quad (\text{A.67})$$

By definition and the BK inequality,

$$\begin{aligned} M^-(x) &= M(p, \gamma) - \mathbf{P}_{p,\gamma}(e \text{ or } f \text{ is occ. and piv. for } x \longleftrightarrow \mathcal{G}) \\ &\geq M(p, \gamma)(1-2p). \end{aligned} \quad (\text{A.68})$$

It follows from (A.66)–(A.68) and the upper bound $M^-(x) \leq M(p, \gamma)$ that

$$\begin{aligned} \mathbf{P}_{p,\gamma}^-(W) &\geq M(p, \gamma) \sum_{A: \bar{e} \notin A} \mathbf{P}_{p,\gamma}^-(\mathcal{C}(\bar{e}) = A, \bar{e} \longleftrightarrow \mathcal{G}) \left[(1-2p) - \sum_{y \in A} \tau_p(\bar{f}, y) \right] \\ &= M(p, \gamma) \left[M^-(\bar{e})(1-2p) - \sum_{y \in V^-} \tau_p(\bar{f}, y) \mathbf{P}_{p,\gamma}^-(\bar{e} \longleftrightarrow y, \bar{e} \longleftrightarrow \mathcal{G}) \right]. \end{aligned} \quad (\text{A.69})$$

It is not difficult to show, using the BK inequality, that

$$\mathbf{P}_{p,\gamma}^-(\bar{e} \longleftrightarrow y, \bar{e} \longleftrightarrow \mathcal{G}) \leq \sum_{w \in V^-} \tau_p(\bar{e}, w) \tau_p(w, y) M^-(w), \quad (\text{A.70})$$

and hence, by (A.68)–(A.69),

$$\begin{aligned} \mathbf{P}_{p,\gamma}^-(W) &\geq M(p, \gamma) [M^-(\bar{e})(1-2p) - \sum_{y, w \in V^-} \tau_p(\bar{f}, y) \tau_p(\bar{e}, w) \tau_p(w, y) M^-(w)] \\ &\geq M^2(p, \gamma) [(1-2p)^2 - \nabla_p^{\max}]. \end{aligned}$$

This completes the proof of (A.57). \square

A.6. Derivation of (A.7). In this section, we prove (A.7), which is an adaptation of the proof of the related inequality

$$M \leq \gamma \frac{\partial M}{\partial \gamma} + M^2 + pM \frac{\partial M}{\partial p}, \quad (\text{A.71})$$

which is proved in [1] (see also [27, Lemma (5.53)]). The main difference between (A.71) and (A.7) is in the precise constants. Indeed, we have that $pm \approx 1$ and $M \gg \gamma$, so that, (A.7) is morally equivalent to

$$M \leq \gamma \frac{\partial M}{\partial \gamma} + \frac{1}{2} M^2 + \frac{1}{2} pM \frac{\partial M}{\partial p}, \quad (\text{A.72})$$

i.e., in the inequality in (A.71) the last two terms are multiplied by 1/2.

We follow the proof of [27, Lemma (5.53)] as closely as possible, deviating only when necessary. Indeed,

$$M(p, \gamma) = \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} \neq \emptyset) = \mathbf{P}_{p,\gamma}(|\mathcal{C}(0) \cap \mathcal{G}| = 1) + \mathbf{P}_{p,\gamma}(|\mathcal{C}(0) \cap \mathcal{G}| \geq 2). \quad (\text{A.73})$$

The first term on the r.h.s. of (A.73) equals $\gamma \frac{\partial M}{\partial \gamma}$, as derived in [27, (5.69)]. For the second term, we define A_x to be the event that either $x \in \mathcal{G}$ or that x is connected by an occupied path to a vertex $g \in \mathcal{G}$. Then,

$$\begin{aligned} \mathbf{P}_{p,\gamma}(|\mathcal{C}(0) \cap \mathcal{G}| \geq 2) &= \mathbf{P}_{p,\gamma}(A_0 \circ A_0) \\ &\quad + \mathbf{P}_{p,\gamma}(|\mathcal{C}(0) \cap \mathcal{G}| \geq 2, A_0 \circ A_0 \text{ does not occur}). \end{aligned} \quad (\text{A.74})$$

In the derivation of (A.71), we simply apply the BK-inequality to obtain

$$\mathbf{P}_{p,\gamma}(A_0 \circ A_0) \leq \mathbf{P}_{p,\gamma}(A_0)^2 = M(p, \gamma)^2, \quad (\text{A.75})$$

leading to the second term in (A.71). Instead, we split, depending on whether $0 \in \mathcal{G}$ or not. If $0 \in \mathcal{G}$, then $0 \in \mathcal{G}$ occurs disjointly from A_0 , so that the BK-inequality yields

$$\mathbf{P}_{p,\gamma}(A_0 \circ A_0, 0 \in \mathcal{G}) \leq \mathbf{P}_{p,\gamma}(A_0 \circ \{0 \in \mathcal{G}\}) \leq \gamma \mathbf{P}(A_0) = \gamma M(p, \gamma). \quad (\text{A.76})$$

When, instead, $0 \notin \mathcal{G}$, there must be *at least two* neighbors e of the origin for which the event

$$A_e \circ A_0 \circ \{(0, e) \text{ occ.}\} \quad (\text{A.77})$$

occurs. Therefore, we can bound, with N denoting the number of neighbors e for which the event in (A.77) occurs, so that $N \geq 2$ a.s. and Markov's inequality yields

$$\begin{aligned} \mathbf{P}_{p,\gamma}(A_0 \circ A_0, 0 \notin \mathcal{G}) &\leq \sum_{e \sim 0} \mathbb{E}_{p,\gamma} \left[\frac{1}{N} \mathbb{1}_{\{A_e \circ A_0 \circ \{(0, e) \text{ occ.}\}\}} \right] \\ &\leq \frac{1}{2} \sum_{e \sim 0} \mathbf{P}_{p,\gamma}(A_e \circ A_0 \circ \{(0, e) \text{ occ.}\}). \end{aligned} \quad (\text{A.78})$$

Therefore, again by the BK-inequality,

$$\mathbf{P}_{p,\gamma}(A_0 \circ A_0, 0 \notin \mathcal{G}) \leq \frac{1}{2} \sum_e \mathbf{P}_{p,\gamma}(A_e) \mathbf{P}_{p,\gamma}(A_0) p = \frac{1}{2} pm M(p, \gamma)^2,$$

so that

$$\mathbf{P}_{p,\gamma}(A_0 \circ A_0) \leq \frac{1}{2} pmM(p,\gamma)^2 + \gamma M(p,\gamma), \quad (\text{A.79})$$

which yields the second term in (A.7).

We move on to the bound on the probability of the event that $|\mathcal{C}(0) \cap \mathcal{G}| \geq 2$, but that $A_0 \circ A_0$ does not occur. This event is equivalent to the existence of an edge $b = (x, y)$ for which the following occurs:

- (i) the edge b is occupied; and
- (ii) in the subgraph of G obtained by deleting b , the following events occur:
 - (a) no vertex of \mathcal{G} is joined to the origin by an open path;
 - (b) x is joined to 0 by an occupied path;
 - (c) the event $A_y \circ A_y$ occurs.

The events in (ii) are independent of the occupation status of the edge $b = (x, y)$ so that

$$\begin{aligned} \mathbf{P}_{p,\gamma}(|\mathcal{C}(0) \cap \mathcal{G}| \geq 2, A_0 \circ A_0 \text{ does not occur}) & \quad (\text{A.80}) \\ &= \frac{p}{1-p} \sum_{x \sim y} \mathbf{P}_{p,\gamma}((x, y) \text{ closed}, x \in \mathcal{C}(0), \mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y) \\ &\leq \frac{p}{1-p} \sum_{x \sim y} \mathbf{P}_{p,\gamma}(x \in \mathcal{C}(0), \mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y), \end{aligned}$$

where we write $x \sim y$ to denote that (x, y) is a bond. We condition on $\mathcal{C}(0)$ to obtain

$$\begin{aligned} \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y) & \quad (\text{A.81}) \\ &= \frac{p}{1-p} \sum_{x \sim y} \sum_A \mathbf{P}_{p,\gamma}(\mathcal{C}(0) = A) \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y \mid \mathcal{C}(0) = A), \end{aligned}$$

where the sum over A is over all sets of vertices which contain 0 and x but not y . Conditionally on $\mathcal{C}(0) = A$, the events $\mathcal{C}(0) \cap \mathcal{G} = \emptyset$ and $A_y \circ A_y$ are *independent*, since $\mathcal{C}(0) \cap \mathcal{G} = \emptyset$ is defined on the vertices in A , while $A_y \circ A_y$ depends on the vertices in A^c and the edges between them. Thus,

$$\begin{aligned} \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y \mid \mathcal{C}(0) = A) & \quad (\text{A.82}) \\ &= \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} = \emptyset \mid \mathcal{C}(0) = A) \mathbf{P}_{p,\gamma}(A_y \circ A_y \text{ off } A), \end{aligned}$$

where we write $\{A_y \circ A_y \text{ off } A\}$ for the event that $A_y \circ A_y$ occurs in the graph where all edges with at least one endpoint in the set A are removed. So far, the derivation equals that in the proof of [27, Lemma (5.53)]. Now we shall deviate. We split, depending on whether $y \in \mathcal{G}$ or not, to obtain

$$\mathbf{P}_{p,\gamma}(A_y \circ A_y \text{ off } A) = \mathbf{P}_{p,\gamma}(A_y \circ A_y \text{ off } A, y \in \mathcal{G}) + \mathbf{P}_{p,\gamma}(A_y \circ A_y \text{ off } A, y \notin \mathcal{G}).$$

When $y \in \mathcal{G}$,

$$\{A_y \circ A_y \text{ off } A, y \in \mathcal{G}\} = \{(\{y \in \mathcal{G}\} \circ A_y) \text{ off } A\}, \quad (\text{A.83})$$

so that, by the BK-inequality,

$$\mathbf{P}_{p,\gamma}(A_y \circ A_y \text{ off } A, y \in \mathcal{G}) \leq \gamma \mathbf{P}_{p,\gamma}(A_y \text{ off } A). \quad (\text{A.84})$$

As a result,

$$\begin{aligned}
& \frac{p}{1-p} \sum_{x \sim y} \mathbf{P}_{p,\gamma}(x \in \mathcal{C}(0), \mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y, y \in \mathcal{G}) \\
& \leq \frac{\gamma p}{1-p} \sum_{x \sim y} \sum_A \mathbf{P}_p(\mathcal{C}(0) = A) \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} = \emptyset \mid \mathcal{C}(0) = A) \mathbf{P}_{p,\gamma}(A_y \text{ off } A) \\
& = \frac{\gamma p}{1-p} \sum_{x \sim y} \sum_A \mathbf{P}_p(\mathcal{C}(0) = A) \mathbf{P}_{p,\gamma}(\mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \mid \mathcal{C}(0) = A) \\
& = \frac{\gamma p}{1-p} \sum_{x \sim y} \mathbf{P}_{p,\gamma}(x \in \mathcal{C}(0), \mathcal{C}(0) \cap \mathcal{G} = \emptyset, \mathcal{C}(y) \cap \mathcal{G} \neq \emptyset) = \gamma p \frac{\partial M}{\partial p},
\end{aligned} \tag{A.85}$$

where the first equality follows again by conditional independence, and the last equality by the fact that (see [27, (5.67)])

$$(1-p) \frac{\partial M}{\partial p} = \sum_{x \sim y} \mathbf{P}_{p,\gamma}(x \in \mathcal{C}(0), \mathcal{C}(0) \cap \mathcal{G} = \emptyset, \mathcal{C}(y) \cap \mathcal{G} \neq \emptyset). \tag{A.86}$$

We are left to bound the contribution where $y \notin \mathcal{G}$. For this, we note that when $A_y \circ A_y$ occurs off A and $y \notin \mathcal{G}$, then there must be *at least two* neighbors z of y for which the event

$$\{(A_z \circ A_y \circ \{(y, z) \text{ occ.}\}) \text{ off } A\} \tag{A.87}$$

occurs. Therefore, by a similar argument as in (A.78),

$$\mathbf{P}_{p,\gamma}(A_y \circ A_y \text{ off } A, y \notin \mathcal{G}) \leq \frac{1}{2} \sum_{z \sim y} \mathbf{P}_{p,\gamma}(\{(A_z \circ A_y \circ \{(y, z) \text{ occ.}\}) \text{ off } A\}). \tag{A.88}$$

By the BK-inequality,

$$\begin{aligned}
\mathbf{P}_{p,\gamma}(\{(A_z \circ A_y \circ \{(y, z) \text{ occ.}\}) \text{ off } A\}) & \leq p \mathbf{P}_{p,\gamma}(A_z \text{ off } A) \mathbf{P}_{p,\gamma}(A_y \text{ off } A) \\
& \leq p M(p, \gamma) \mathbf{P}_{p,\gamma}(A_y \text{ off } A).
\end{aligned}$$

Repeating the steps in (A.85), we thus arrive at

$$\frac{p}{1-p} \sum_{x \sim y} \mathbf{P}_{p,\gamma}(x \in \mathcal{C}(0), \mathcal{C}(0) \cap \mathcal{G} = \emptyset, A_y \circ A_y, y \notin \mathcal{G}) \leq \frac{1}{2} m p^2 M(p, \gamma) \frac{\partial M}{\partial p}. \tag{A.89}$$

Therefore, summing the two bounds in (A.85) and (A.89), we arrive at

$$\mathbf{P}_{p,\gamma}(|\mathcal{C}(0) \cap \mathcal{G}| \geq 2, A_0 \circ A_0 \text{ does not occur}) \leq \left[\frac{1}{2} m p M(p, \gamma) + \gamma \right] p \frac{\partial M}{\partial p},$$

which is the third term in (A.7). This completes the proof of (A.7). \square
