ABSTRACT

We consider the tail behavior of the response time distribution in an $M/G/1$ queue with heavy-tailed job sizes, specifically those with intermediate regularly varying tails. In this setting, the response time tail of many individual policies has been characterized, and it is known that policies such as Shortest Remaining Processing Time (SRPT) and Foreground-Background (FB) have response time tails of the same order as the job size tail, and thus such policies are tail-optimal. Our goal in this work is to move beyond individual policies and characterize the set of policies that are tail-optimal. Toward that end, we use the recently introduced SOAP framework to derive sufficient conditions on the form of prioritization used by a scheduling policy that ensure the policy is tail-optimal. These conditions are general and lead to new results for important policies that have previously resisted analysis, including the Gittins policy, which minimizes mean response time among policies that do not have access to job size information. As a by-product of our analysis, we derive a general upper bound for fractional moments of $M/G/1$ busy periods, which is of independent interest.

1 INTRODUCTION

The scheduling of jobs in single server queues has been an important topic of study over the past decades. On one hand, much attention has been devoted to identifying scheduling policies that minimize the mean response time in a variety of settings. For example, in preemptive settings it is widely known that Shortest Remaining Processing Time (SRPT) minimizes the mean response time [21] regardless of the job size distribution when job sizes are known to the scheduler. When sizes are unknown to the scheduler but the job size distribution is known, the optimal scheduling policy is the Gittins policy, which serves the job with maximum Gittins index [2]. If the job size distribution is also unknown, then the Randomized Multi-Level Feedback (RMLF) policy minimizes the competitive ratio for mean response time [14].

On the other hand, in many applications it is important to avoid large response times, not just minimize the mean response time. Thus, significant research has been devoted to analyzing the distribution of response times under a large variety of scheduling policies, ranging from classical policies such as First Come First Served (FCFS) and SRPT, to newer ones such as Processor Sharing (PS) and its many generalizations [1, 3, 17]. In some simple settings it is possible to precisely characterize the response time distribution, but in general research focuses on characterizing the tail of the response time distribution.

The task of characterizing the response time tail is more complex than that of optimizing the mean response time. Initially, response time tail asymptotics were studied in the case of light-tailed job size distributions, e.g., [9, 17, 25] and the references therein. In this context, it has been shown that FCFS maintains the optimal (lightest) tail of the response time distribution, whereas under SRPT the response time tail is the heaviest possible under any work conserving scheduling policy. This is a stark contrast to the optimality of SRPT for the mean response time.

While the focus of response time tail asymptotics was initially on light-tailed settings, a shift occurred in the late nineties when it was observed that heavy-tailed distributions occur frequently in computer and communications systems, e.g., in file sizes in the web [11], in I/O patterns [20], the length of network sessions [19], and more. These observations triggered significant research into the impact of heavy-tailed phenomena on the design and performance of computer and communications systems. The resulting literature has demonstrated that heavy-tailed traffic characteristics have a dramatic effect on the waiting times and response times experienced by users and that scheduling and priority mechanisms need to be designed with heavy-tailed phenomena in mind.

A key observation from the research that followed is that scheduling policies that perform well under light-tailed settings may not perform well under heavy-tailed settings, and vice versa. A prime example is FCFS, which has the optimal response time tail under light-tailed job sizes [25], but has a response time tail as bad as possible among work conserving policies under heavy-tailed job sizes. More precisely, assume that a job size $X$ is regularly varying with index $\alpha$ and denote this with $\text{RV}(\alpha)$. Then, the response time in a $GI/GI/1$ FCFS queue is known to be $\text{RV}(1-\alpha)$ [10]. A worse index is not possible under work-conserving policies since the residual busy period of such a queue is $\text{RV}(1-\alpha)$. The response time in a $GI/GI/1$ SRPT queue, on the other hand, has the same index as the job size ($-\alpha$) in this setting. Since the response time of a job can never be smaller than its size, the response time index $-\alpha$ is optimal. So, SRPT is optimal in this heavy-tailed setting, whereas FCFS performs the worst in terms of response time tail index – the exact opposite of the light-tailed scenario.

---

1 A scheduling policy is work conserving if it always uses the server at full speed whenever a job is present in the system.

2 A random variable $X$ is regularly varying with index $-\alpha$ if $P(X > x) = L(x)x^{-\alpha}$, where the function $L(\cdot)$ is slowly varying, i.e., $L(ax)/L(x) \to 1$ for any $a > 0$.
Observations like this have led to significant research on the impact of the service discipline on delay asymptotics; cf. the surveys [7, 9]. Given the prominence of heavy-tailed phenomena in computer and communications systems, a driving question for the community has been to characterize which policies have the optimal response time tail asymptotics, i.e., which policies have a response time tail that is of the same order as the tail of the job size distribution under regularly varying job sizes. This notion of “tail equivalence” (also referred to as tail optimality) has driven research for decades and at this point there is a variety of common policies that have been shown to be tail equivalent, including Processor Sharing (PS) [27], Foreground-Background (FB) [16], and Preemptive Shortest Job First (PSJF) [16].

However, despite significant progress, there are still many important policies for which we do not know if they are tail equivalent or not. Examples are the Gittins policy and RMLF. Further, no precise characterization of which properties a scheduling policy must have in order to be tail equivalent is known.

The first attempt at a general set of conditions that ensure tail equivalence was [16], which provided analytic conditions that can be used to simplify the analysis of scheduling policies when studying the response time tail. It was these analytic conditions that enabled the first analysis of policies such as SRPT, PSJF, and FB.

However, the conditions are defined in terms of the analysis of the policy rather than the prioritization rules used by the policy, and so they do not provide insight into which policies are tail equivalent. For that, the most general result to this point is from [18], which introduces a set of properties based on job sizes that are sufficient conditions for tail equivalence. These properties ensure that the scheduler always prioritizes jobs with small sizes and are satisfied by both SRPT and PSJF, but not by policies that do not make use of job sizes, such as Gittins, RMLF, FB, etc. Thus, there is a considerable gap between the sufficient conditions outlined by [18] and a general characterization of tail-equivalent scheduling policies.

Contributions
In this paper, we provide sufficient conditions that ensure optimality of the tail of the response time distribution (a.k.a. tail equivalence) for scheduling policies in M/GI/1 queues with job size distributions that are intermittently regularly varying. Our results provide guidelines on how scheduling policies can perform prioritization in order to ensure tail equivalence without having access to job sizes, and are thus complementary to the conditions in [18], which focus on prioritization based on job size. The conditions are general and are satisfied by important policies such as the Gittins and RMLF policies, for which no previous analysis of the response time tail is known. Additionally, the sufficient conditions are satisfied by policies that use limited preemption, for the first time highlighting the preemption frequency needed to achieve tail-optimality.

The key building block underlying the sufficient conditions we develop is the SOAP (Schedule Ordered by Age-based Priority) framework, recently introduced in [23]. In the SOAP framework, scheduling policies are expressed as rank functions which assign a rank to each job and serve the job with lowest rank. A job’s rank is determined by a function of its age (the amount of time the job has already received service), and a job-specific descriptor, e.g., the size or priority level of the job. Using this framework, our sufficient conditions for tail equivalence are defined in terms of the rank function of a policy. The formal conditions can be found in Section 3, but intuitively the conditions ensure that old jobs do not receive priority over other jobs for too long. Specifically, for a job \( J \), part one of the condition bounds the consecutive time that other jobs will outrank \( J \), and part two bounds the first age at which jobs will never in the future outrank \( J \).

In general, there are three typical approaches for proving tail equivalence, see [7] for a survey. The first relies on a relationship between the tail behavior of a random variable \( Y \) and the behavior of its Laplace-Stieltjes transform (LST) \( E[e^{-sY}] \) for \( s \downarrow 0 \) ([6], p. 333). An expression for the response time LST of the single server queue under SOAP is indeed available (see [23]); however, it depends in such an intricate way on the rank function that this approach proved unsuitable for determining the tail behavior of the response time. Another common approach is to perform a sample path analysis of the policies, as was pursued by [18]. However, again, the form of dependence in the rank function makes this difficult. Hence, in proving our main result, Theorem 3.3, we have adapted the probabilistic method developed by Núñez-Queija [16], which exploits a Markov-type inequality. While the method of [16] does not apply directly off-the-shelf, we are able to extend it to apply to the analysis of our sufficient conditions. This extension requires technical effort and, in particular, relies on a new analysis of the fractional moments of busy periods that is of independent interest (see Theorem 5.4).

To conclude, we summarize the contributions of the paper below:

- We provide a set of sufficient conditions for tail equivalence, i.e., optimality of the response time tail, when job sizes are intermittently regularly varying for policies that do not have access to job size information. These conditions highlight that tail equivalence depends on imposing a bound on the amount of consecutive time that a job has priority over others.
- Our sufficient conditions provide the first proof of tail equivalence for a number of well-known scheduling policies, including the Gittins policy, RMLF, and the Shortest Expected Remaining Processing Time first (SERPT) policy. Tail equivalence of these policies is a long-standing open question given their optimality among policies that do not use precise job size information.
- Our sufficient conditions provide the first insight into how much preemption is needed in order to maintain tail equivalence. We specifically state which preemption frequencies guarantee tail optimality.
- Our proof of sufficiency includes an interesting foundational result for M/GI/1 queues: a bound on the fractional moments of the M/GI/1 busy period. Previously, only expressions for its integer moments were known.

2 SYSTEM MODEL AND PRELIMINARIES
We consider an M/GI/1 queue with arrival rate \( \lambda \) and job size \( X \). We write \( F(x) = P(X \leq x) \) and \( \overline{F}(x) = 1 - F(x) \) for the distribution function and tail of \( X \), respectively. The system load is denoted
Characterizing Policies with Optimal Response Time Tails under Heavy-Tailed Job Sizes

by \( \rho = \lambda E[X] < 1 \). We write \( T \) for response time and \( T_X \) for size-
conditional response time, that is, the response time for jobs of size \( x \). Our focus is on the case where \( X \) is heavy-tailed. Specifically, we study the following class of heavy-tailed distributions.

**Assumption 2.1.**

(i) The tail \( F(\cdot) \) is immediately regularly varying, meaning

\[
\liminf_{x \to 0^+} \liminf_{x \to \infty} \frac{F((1 + r)x)}{F(x)} = 1.
\]

(ii) There exist \( \beta > \alpha > 1 \) such that the upper and lower Matuszewska indices of \( F(\cdot) \) are in \((-\beta, -\alpha)\).

The class of immediately regularly varying functions contains the class of regularly varying functions [12], which in turn contains Pareto distributions and power law distributions, among others. Roughly speaking, one can think of Assumption 2.1 as saying that \( F(\cdot) \) is bounded between two power law distributions, as the following Potter bound formalizes.

**Lemma 2.2 ([6, Proposition 2.2.1]).** If Assumption 2.1 holds, then there exist constants \( C, x_0 > 0 \) such that for all \( x_2 \geq x_1 \geq x_0 \),

\[
\frac{1}{C} \left( \frac{x_2}{x_1} \right)^{-\beta} \leq \frac{F(x_2)}{F(x_1)} \leq C \left( \frac{x_2}{x_1} \right)^{-\alpha}.
\]

The scheduling policies we study in this work are SOAP policies, a broad class of policies introduced by Scully et al. [23]. A SOAP policy is specified by a rank function \( r : \mathbb{R}_+ \to \mathbb{R} \) mapping a job’s age, which is the amount of time it has been served, to its rank, which is its priority level. All SOAP policies have the same core scheduling rule: at every moment in time, always serve the job of minimum rank, breaking ties first-come, first-served. We assume a preemptive-resume model with no preemption overhead. We discuss SOAP policies in more detail, including how to analyze their response time, in Section 6.

**3 OVERVIEW OF RESULTS**

Our main result, Theorem 3.3, gives sufficient conditions for tail optimality in terms of properties of the rank function in SOAP. Thus, it characterizes properties of the prioritization of policies that guarantee optimal tail behavior. We first state a version of our main theorem in which the condition for tail optimality is slightly simplified. It states that a policy is tail-optimal if its rank function is bounded between two power functions in a specific way.

**Theorem 3.1 (Simplified Result).** Consider an \( M/G/1 \) queue whose job size distribution obeys Assumption 2.1 using a SOAP scheduling policy whose rank function obeys

\[
r(a) \in \Omega(a^\delta) \cap O(a^\alpha)
\]

for some \( \delta > \gamma > 0 \). If

\[
\frac{\delta}{\gamma} - \frac{\gamma}{\delta} < \frac{\alpha - 1}{\beta},
\]

then the policy is tail-optimal, i.e.,

\[
\lim_{x \to \infty} \frac{1}{F(x)} P\{T > \frac{x}{1-\rho}\} = 1.
\]

The condition of Theorem 3.1 is easy to interpret and is suitable for tail-optimality proofs for many of the policies presented in Section 3. However, the result holds under more general conditions. To state these conditions formally, we need some notation. Let

- \( w_x \) be the worst rank attained by a job of size \( x \),
- \( y_x \leq x \) be the earliest age with rank \( w_x \),
- \( z_x \geq x \) be the earliest age after \( x \) with rank \( \geq w_x \), and
- \( u_x \geq z_x \) be the latest age with rank \( \leq w_x \).

Figure 3.1 illustrates these quantities and they are defined formally in Definitions 6.2, 6.11 and 6.13.

Our sufficient conditions on the rank function are defined in terms of two quantities: \( z_x - y_x \) and \( w_x \).

**Assumption 3.2.**

(i) There exists \( \zeta \in [0, \infty) \) such that \( z_x - y_x = O(x^\zeta) \).

(ii) There exists \( \eta \in [\max\{1, \zeta\}, \infty) \) such that \( u_x = O(x^\eta) \).

Intuitively, \( \zeta \) and \( \eta \) have the following interpretation. First, the smaller \( \zeta \) is, the more quickly the system can preempt jobs. Second, the smaller \( \eta \) is, the more each job is shielded from getting stuck behind larger jobs. Note that any rank function trivially satisfies Assumption 3.2 with \( \zeta = \eta = \infty \), but, as suggested by the interpretations above, we would like \( \zeta \) and \( \eta \) to be small. Our main result states just how small \( \zeta \) and \( \eta \) need to be to ensure tail optimality.

**Theorem 3.3 (Main Theorem).** Consider an \( M/G/1 \) queue whose job size distribution obeys Assumption 2.1 and a SOAP scheduling policy whose rank function obeys Assumption 3.2. If

\[
\zeta - 1 < \frac{\alpha - 1}{\beta},
\]

then the policy is tail-optimal, i.e.,

\[
\lim_{x \to \infty} \frac{1}{F(x)} P\{T > \frac{x}{1-\rho}\} = 1.
\]

As we prove now, Theorem 3.3 immediately implies its simplified version, Theorem 3.1.

**Proof of Theorem 3.1.** Precomposing any strictly increasing function with the rank function \( r \) yields an equivalent rank function that encodes the same SOAP policy, so we may assume without loss of generality that

\[
r(a) \in \Omega(a^{\delta/\gamma}) \cap O(a).
\]

This implies \( w_x = O(x) \) and thus \( u_x = O(x^{\delta/\gamma}) \). Therefore, Assumption 3.2 holds with \( \zeta = \eta = \delta/\gamma \), so tail optimality follows from Theorem 3.3.\( \square \)
To illustrate the generality of the sufficient conditions in Theorem 3.3, consider FB be the length of a busy period with initial work $U$. Thus, a standard busy period would be $B_X$. We develop the following representation of the $n$th moment of a busy period for $n \in \mathbb{Z}_+$:

\[
E[B^*_X] = \sum_{i=1}^J d_i \frac{E[X_j]}{(1-\rho)^{a_i}} \prod_{j=1}^I dE[X_{ij}],
\]

where $I, J, a_i, b_i, c_i, d_i \in \mathbb{Z}_+$ are constants that depend on $n$ (see Lemma 5.2 and Corollary 5.3). Moreover, we show that this representation extends in a natural way to fractional moments of order $p = n - q > 0$, where $q \in (0, 1)$. Instead of equality, we obtain an upper bound in the case of fractional moments. We defer the full statement, which requires heavy notation, to Theorem 5.4.

Applications of Theorems 3.1 and 3.3

To illustrate the generality of the sufficient conditions in Theorems 3.1 and 3.3, we consider how they can be applied to understand the response time tail of common policies. In this section, we illustrate the application of the theorems to understand tail optimality for policies where no analysis is known. We focus on four examples: FB with limited preemption, Gittins, SERPT, and RMLF.

3.1 FB with Limited Preemption

Our first example focuses on a policy that is known to be tail optimal—FB—but limits the amount of preemption it may use. We consider FB here, but the same analysis can be performed for other policies that satisfy the conditions of Theorem 3.3. FB is particularly interesting because it is the optimal policy for job size distributions with a decreasing failure rate when no job size information is known. FB works by always serving the job of least age, sharing the processor equally in the case of ties. That is, FB is the SOAP policy with rank function $r(a) = a$ [23, Example 3.1]. As a result, it preempts jobs frequently and rarely works on a single job without interruption. In situations where there is a cost to preemption this is a significant drawback. Thus, it is important to understand the performance of FB when preemption is limited.

To this end, we study a variation of FB with limited preemption (FB-LP) where preemption a job is only allowed when its age is one of a limited set of checkpoints $A \subseteq \mathbb{R}_+$. Specifically, FB-LP is the SOAP policy with rank function

\[
r(a) = \begin{cases} 
  a + 2 & \text{if } a \in A \\
  1 & \text{otherwise}.
\end{cases}
\]

Figure 3.2 illustrates an example of FB-LP where $A$ is a sequence $a_0 = 0, a_1, a_2, \ldots$.

The design of the FB-LP policy amounts to choosing the set of checkpoints $A$. In the extreme where $A = \mathbb{R}_+$, FB-LP is the same as using ordinary FB, which is tail-optimal but has frequent preemption and processor sharing. In the other extreme, setting $A = \emptyset$ is the same as using FCFS, which never preempts jobs but has pessimal response time tail behavior [10]. We therefore ask:

**How frequently must checkpoints occur in order to ensure tail optimality?**

We can answer this question using Theorem 3.3.

Consider a sequence of checkpoints $A = \{0, a_1, a_2, \ldots\}$. When $x \in (a_i, a_{i+1}]$, we have $x = a_i$ and $z_x = a_{i+1}$, as shown in Figure 3.2. This means if $a_{i+1} - a_i = O(a_i^\zeta)$, then Assumption 3.2 holds with the same value of $\zeta$ and $\eta = \infty$. By Theorem 3.3, tail optimality holds if $\zeta < (a - 1)/\beta$, implying the following result.

**Corollary 3.4.** Consider an $M/G/1$ queue whose job size distribution obeys Assumption 2.1. The FB-LP policy with checkpoints $a_0 = 0, a_1, a_2, \ldots$ is tail-optimal if

\[
a_{i+1} - a_i = O(a_i^\zeta)
\]

for some $\zeta < (a - 1)/\beta$.

3.2 The Gittins Policy

Our next example application of Theorem 3.3 is the Gittins policy, which is the policy that minimizes mean response time of the $M/G/1$ queue when the job size distribution is known but individual job sizes are unknown. Gittins can be viewed as a SOAP policy whose rank function depends on the job size distribution [23, Example 3.7]:

\[
r(a) = \inf_{b \geq a} \frac{\int_a^b F(t) \, dt}{F(a) - F(b)}. \tag{3.2}
\]

While Gittins is known to be optimal for the mean response time, the response time tail behavior of Gittins has resisted analysis. In this section, we show that, under Assumption 2.1 and an additional technical condition, the Gittins policy is tail-optimal.

Given Theorem 3.1, it suffices to bound the Gittins rank function. Because $b = \infty$ is a possibility for the infimum in (3.2), by Lemma 2.2,

\[
r(a) \leq \int_a^\infty \frac{F(t)}{F(a)} \, dt \leq O(1) \int_a^\infty \left(\frac{t}{a}\right)^{-\alpha} \, dt = O(a). 
\]

By Theorem 3.1, Gittins is tail-optimal if its rank function satisfies $r(a) = O(a^\gamma)$, where $\frac{1}{\gamma} - \gamma < \frac{m - 1}{\beta}$. However, this is not the case for all job size distributions satisfying Assumption 2.1. For example,
Characterizing Policies with Optimal Response Time Tails under Heavy-Tailed Job Sizes

if the job size distribution has positive mass at some value x, then Gittins has \( r(x^-) = 0 \).

Fortunately, under a mild additional condition, we can prove a lower bound on the Gittins rank function. Suppose that for sufficiently large x, the job size distribution has a well defined density \( f(x) = -\frac{d}{dx} F(x) \) and hazard rate \( h(x) = f(x)/F(x) \). Then for sufficiently large ages \( a \),

\[
\begin{align*}
    r(a) &= \inf_{b > a} \int_a^b \frac{F(t)}{F(a) - F(b)} dt \\
    &= \inf_{b > a} \int_a^b \frac{h(t)F(t)}{F(a) - F(b)} dt \\
    &\geq \inf_{b > a} \left( \sup_{c \in (a,b)} h(c) \right) \int_a^b \frac{F(t)}{F(a)} dt \\
    &= \inf_{b > a} \frac{1}{h(b)}.
\end{align*}
\]

This means that if \( h(a) = O(a^{-\gamma}) \) for \( \gamma > 0 \), then \( r(a) = \Omega(a^\gamma) \), so Theorem 3.1 yields the following result.

**Corollary 3.5.** Consider an M/G/1 queue whose job size distribution obeys Assumption 2.1. The Gittins policy is tail-optimal if the job size distribution has hazard rate \( h(x) = O(x^{-\gamma}) \) for some \( \gamma > 0 \) satisfying

\[
\frac{1}{\gamma} - \frac{1}{\gamma} < \frac{1}{\alpha} - \frac{1}{\beta}.
\]

In particular, \( h(x) = O(x^{\min\{1,\beta/(\alpha-1)\}}) \) is sufficient for the Gittins policy to be tail-optimal.

### 3.3 Shortest Expected Remaining Processing Time

Shortest Expected Remaining Processing Time (SERPT) is a variation of SRPT for settings when the precise remaining sizes of jobs are not known, but the expected remaining size can be computed given knowledge of the job size distribution. As the name implies, SERPT always serves whichever job has the least expected remaining size. Like Gittins, SERPT is a SOAP policy whose rank function depends on the job size distribution [23, Example 3.5]:

\[
r(a) = \mathbb{E}[X - a | X > a] = \int_a^{\infty} \frac{F(t)}{F(a)} dt.
\]

We show that SERPT is always tail-optimal. By Lemma 2.2, the rank function is bounded by

\[
\Omega(a) = O(1) \int_a^{\infty} \left( \frac{1}{a} \right)^{-\beta} dt \leq r(a) \leq O(1) \int_a^{\infty} \left( \frac{1}{a} \right)^{-\alpha} dt = O(a),
\]

so Theorem 3.1 implies tail optimality.

The Monotonic SERPT (M-SERPT) policy is a variant of SERPT introduced by Scully et al. [24]. Its rank function is the increasing envelope of SERPT’s:

\[
r(a) = \max_{0 \leq b \leq a} \mathbb{E}[X - b | X > b].
\]

As with SERPT, Lemma 2.2 implies \( r(a) \in \Omega(a) \cap O(a) \) for M-SERPT, so M-SERPT is also tail-optimal.

**Corollary 3.6.** In an M/G/1 queue whose job size distribution obeys Assumption 2.1, SERPT and M-SERPT are both tail-optimal.

The tail optimality of M-SERPT is particularly significant because M-SERPT has mean response time within a factor of 3 of Gittins’s [24], and is simpler to understand and implement. Moreover, unlike our result for Gittins in Corollary 3.5, we require no additional assumptions on the job size distribution to ensure M-SERPT’s tail optimality. Thus, M-SERPT is a policy that, for all distributions satisfying Assumption 2.1, is within a constant factor of optimal for both the mean response time and the tail of the response time.

**Corollary 3.7.** Consider an M/G/1 queue whose job size distribution obeys Assumption 2.1. There exists a policy that is blind to job size information, namely M-SERPT, that is both tail-optimal and a constant-factor approximation for mean response time.

### 3.4 Randomized Multi-Level Feedback

The Randomized Multi-Level Feedback (RMLF) policy is designed to have low mean response time when neither individual job sizes nor the job size distribution is known. Originally introduced in the worst-case scheduling literature [5, 14], RMLF was studied in the stochastic GI/GI/1 setting by Bansal et al. [4], who showed that RMLF is \( O(\log \frac{1}{\rho}) \)-competitive with SRPT for mean response time. However, previous results exist for the tail of the response time under RMLF.

Here, we seek to apply our sufficient condition for tail optimality to RMLF. Unfortunately, RMLF does not fit into the SOAP framework as stated so far because not every job follows the same rank function: each job chooses a random parameter \( v \in [0, 1] \) and then follows rank function

\[
r_v(a) = \min\{2^n | n \in \mathbb{N}, 2^{na}v > a \}.
\]

Nevertheless, we still have \( \frac{a}{2} \leq r_v(a) \leq 2a \) for all ages \( a \geq 1 \) and parameters \( v \in [0, 1] \), so it seems that some adaptation of Theorem 3.1 ought to imply tail optimality of RMLF. This is indeed the case, but stating the adaptation requires some new terminology.

While RMLF is not a SOAP policy, it is what [22] calls a SOAP Bubble policy. The SOAP Bubble class of policies is a superset of the SOAP class. Much like SOAP, under a SOAP Bubble policy, every job’s rank is a function of its age, and the system always serves the job of minimal rank, but different jobs can have different rank functions. Specifically, a SOAP Bubble policy is characterized by lower and upper rank functions \( r^-, r^+ : \mathbb{R}_+ \rightarrow \mathbb{R} \), and the rank function \( r_j \) of each job \( j \) can be any function obeying \( r^- \leq r^j(a) \leq r^+(a) \). Therefore, RMLF is a SOAP Bubble policy with lower and upper rank functions

\[
\begin{align*}
    r^-(a) &= \min\{2^n | n \in \mathbb{N}, 2^{na}v > a \} \\
    r^+(a) &= \min\{2^n | n \in \mathbb{N}, 2^{na}v > a \}.
\end{align*}
\]

In Appendix D, we formulate adaptations of Theorems 3.1 and 3.3 that apply to SOAP Bubble policies. For example, Theorem D.3 is the same as Theorem 3.1, except its precondition is \( r^-(a) = \Omega(a^\gamma) \)

---

1The full SOAP framework is general enough to handle some policies with parametrized rank functions, but it requires the parameter to be chosen i.i.d. for each job [23], whereas RMLF draws \( v \in [0, 1] \) using a different distribution for each job in the busy period.
and \( r^*(a) = O(a^{\delta}) \). Applying Theorem D.3 to RMLF with \( \gamma = \delta = 1 \) implies that RMLF is tail-optimal.

Corollary 3.8. In an M/G/1 queue whose job size distribution obeys Assumption 2.1, RMLF is tail-optimal.

4 TAIL OPTIMALITY OF SOAP POLICIES

In the remainder of the paper we present a proof of Theorem 3.3, namely that a SOAP policy is tail-optimal under certain conditions on the rank function. The main steps are presented in this section. Some of these steps rely on technical lemmas, which are introduced in Sections 5–7 and proven in Appendices A and C.

To prove Theorem 3.3, we adapt and extend a result by Núñez-Queija [16], which gives sufficient conditions for tail optimality in terms of the conditional response time of a policy. These conditions are as follows.

**Condition 4.1.** \( T_x \) is stochastically increasing in \( x \).\(^8\)

**Condition 4.2.** We have \( \lim_{x \to \infty} E[T_x]/x = 1/(1 - \rho) \).

**Condition 4.3.**

(i) For all \( \varepsilon > 0 \),

\[
\lim_{x \to \infty} P \left( T_x < \frac{(1 - \varepsilon)x}{1 - \rho} \mid X > x \right) = 0.
\]

(ii) For all \( \varepsilon > 0 \),

\[
\lim_{x \to \infty} \frac{1}{F(x)} P \left( T_x > \frac{(1 + \varepsilon)x}{1 - \rho} \mid X > x \right) = 0.
\]

**Proposition 4.4.** If \( X \) obeys Assumption 2.1 and Conditions 4.1–4.3 hold, then

\[
\lim_{x \to \infty} \frac{1}{F(x)} P \left( T > \frac{x}{1 - \rho} \right) = 1.
\]

Remark. Proposition 4.4 differs from Núñez-Queija [16, Theorem 2.3] in that, instead of assuming Condition 4.3 directly, Núñez-Queija [16, Lemmas 2.1 and 2.2] proves it starting from a stronger condition. This adapted version is more appropriate for our analysis.

The key approach of our proof of Theorem 3.3 is to verify that Conditions 4.1–4.3 of Proposition 4.4 hold if the rank function parameters \( \xi, \eta \) satisfy \( \frac{1}{2} < \frac{\xi}{\eta} < \frac{\eta}{\xi} - 1 \). This is done in six steps below. In Step 1, we relate the tails of Condition 4.3 to moments of \( T_x \). In Step 2, bounds for those moments are derived. Conditions 4.1, 4.2, 4.3(i) and 4.3(ii) are subsequently verified in Steps 3–6.

**Step 1: From tails to moments.**

To relate the tails of Condition 4.3 to moments of \( T_x \), we need the following lemma, which does not rely on any specifics of the M/G/1 model or SOAP.

Let

\[
g^p_x(t) = t^p - E[T_x]^p - pE[T_x]^{p-1}(t - E[T_x]).
\]

We can think of \( g^p_x(t) \) as \( t^p \) minus the first two terms of the Taylor series of \( t^p \) about \( t = E[T_x] \).

**Lemma 4.5.** For all \( p, t > 0 \),

\[
P(T_x > t) \leq \frac{E[T_x]^p - E[T_x]^{p-1}}{g^p_x(t)} \text{ if } t > E[T_x],
\]

\[
P(T_x < t) \leq \frac{E[T_x]^{p-1} - E[T_x]^p}{g^p_x(t)} \text{ if } t < E[T_x].
\]

**Proof.** Note that \( g^p_x(t) \) is decreasing in \( t \) for \( t < E[T_x] \) and increasing for \( t > E[T_x] \). Therefore, if \( t < E[T_x] \), then

\[
P(T_x < t) = P(T_x < t \text{ and } g^p_x(T_x) > g^p_x(t)) \leq P(g^p_x(T_x) > g^p_x(t))
\]

and if \( t > E[T_x] \), then

\[
P(T_x > t) = P(T_x > t \text{ and } g^p_x(T_x) > g^p_x(t)) \leq P(g^p_x(T_x) > g^p_x(t)).
\]

In both cases, Markov’s inequality implies the desired bound. \( \square \)

**Step 2: Moment bounds.**

The bounds presented in this step will be used to verify Conditions 4.2 and 4.3 (Steps 4–6). First, we split a job’s response time \( T_x \) into two independent non-negative components, waiting time \( Q[w_x] \) and residence time \( R_x \) (see Scully et al. [23]):

\[
T_x = Q[w_x] + R_x.
\]

We bound \( E[Q[w_x]] \) and \( E[R_x] \) in Lemmas 4.6 and 4.7 below, subject to the precondition of Theorem 3.3. For more details we refer to Section 7.

In the sequel we use the following notation. We write \( f(x) = \tilde{o}(g(x)) \) if there exists \( \delta > 0 \) such that \( f(x) = o(x^{-\delta} g(x)) \).

**Lemma 4.6.** If (3.1) holds, then there exists \( \beta' > \beta \) such that for all \( p \in (0, \beta') \),

\[
E[Q[w_x]^p] \leq \tilde{o}(x^p),
\]

\[
E[R_x^p] \leq \frac{x}{1 - \rho}^p + \tilde{o}(x^p).
\]

**Lemma 4.7.** If (3.1) holds, then

\[
E[R_x] \geq \frac{x}{1 - \rho} - \tilde{o}(x).
\]

Lemmas 4.6 and 4.7 are essentially restatements of Lemmas 7.3–7.5 (see Section 7). The proofs of these lemmas require additional analysis on SOAP and M/G/1 busy periods, which is the purpose of Sections 5 and 6. Section 5 derives a general bound for fractional busy period moments, and Section 6 describes how to express waiting and residence times in terms of busy periods.

We now use the moment bounds of Lemmas 4.6 and 4.7 for \( Q[w_x] \) and \( R_x \) to obtain moment bounds for \( T_x \).

**Lemma 4.8.** If (3.1) holds, then

\[
E[T_x^p] \leq \left( \frac{x}{1 - \rho} \right)^p + \tilde{o}(x^p) \text{ for all } p \in [1, \beta'),
\]

\[
E[T_x]^p \geq E[R_x]^p \geq \left( \frac{x}{1 - \rho} \right)^p - \tilde{o}(x^p) \text{ for all } p > 0.
\]

---

\(^8\)That is, \( P(T_x > t) \leq P(T_y > t) \) for all \( t \geq 0 \) and all \( 0 \leq x \leq y \).
Proof. Lemma 4.6, Minkowski’s inequality, and the fact that 
\[(x + φ(x))^p = x^p + φ(x^p)\] 
together imply that for all \(p \in [1, β')\),
\[E[T_x^p] \leq \left( E\left[ Q(w_x)^p \right] \right)^{1/p} + E[f^p]^{1/p} \]
\[≤ \left( φ(x) + \left( \frac{x}{1 - ρ} \right)^p + φ(x^p) \right)^{1/p} \]
\[= \left( \frac{x}{1 - ρ} \right)^p + φ(x^p).\]

Lemma 4.7 implies that (4.3) holds for all \(p > 0\). \(\Box\)

A direct consequence of Lemma 4.8 is the following.

Lemma 4.9. If (3.1) holds, then there exists \(p > β\) such that in the \(x \to ∞\) limit, 
\[E[T_x^p] - E[T_x]^p = φ(x^p),\]

Proof. Choose \(p \in (β, β')\) in Lemma 4.8. \(\Box\)

Remark. Núñez-Queija [16] uses a slightly different version of Lemma 4.9, showing that Condition 4.3 holds if there exists \(p > β\) such that \(E[(T_x - E[T_x])^p] = φ(x^p)\). Unfortunately, working with the absolute central moment is difficult unless \(p\) is an even integer, which suffices for the simple class of policies considered by Núñez-Queija [16] but not for the broad class of SOAP policies we consider. Our Lemma 4.9 is easier to work with for odd and fractional \(p\) and, as shown below, still allows us to verify Condition 4.3.

Step 3: Verification of Condition 4.1.
Condition 4.1 is immediate for all SOAP policies (see Lemma 6.15).

Step 4: Verification of Condition 4.2.
Condition 4.2 follows from choosing \(p = 1\) in Lemma 4.8.

Step 5: Verification of Condition 4.3(i).

Let \(p > β\) be as in Lemma 4.9. By Condition 4.2,
\[\lim_{x \to ∞} \frac{1}{x^p} \left( \frac{1 ± ϵ x}{1 - ρ} \right) = \lim_{x \to ∞} \frac{1}{x^p} \left( \frac{(1 ± ϵ x)^p}{1 - ρ} - E[T_x]^p \right) \]
\[- p E[T_x]^{p-1} \left( \frac{(1 ± ϵ x)}{1 - ρ} - E[T_x] \right) \]
\[= \frac{(1 ± ϵ)^p - 1 - p(1 ± ϵ - 1)}{(1 - ρ)^p} \]
\[= \frac{(1 ± ϵ)^p - (1 ± ϵ p)}{(1 - ρ)^p} \]
\[> 0,\]

and therefore
\[g_x^p \left( \frac{(1 ± ϵ) x}{1 - ρ} \right) = Ω(x^p). \quad (4.4)\]

Combining this with Condition 4.1 and Lemma 4.5 implies Condition 4.3(i):
\[\lim_{x \to ∞} P\left\{ T_x > \left( \frac{1 ± ϵ x}{1 - ρ} \right) \right\} = \lim_{x \to ∞} P\left\{ T_x < \left( \frac{(1 ± ϵ) x}{1 - ρ} \right) \right\} \]
\[≤ \lim_{x \to ∞} \frac{E[T_x^β]}{g_x^β \left( \frac{(1 ± ϵ) x}{1 - ρ} \right)} \]
\[= \lim_{x \to ∞} \frac{\left( \frac{x}{1 - ρ} \right)^β - \left( \frac{x}{1 - ρ} \right)^β + φ(x^p)}{Ω(x^p)} \]
\[= 0.\]

Step 6: Verification of Condition 4.3(ii).

We begin by applying Lemma 4.5:
\[P\left\{ T_x > \left( \frac{1 ± ϵ x}{1 - ρ} \right) \right\} \]
\[≤ \int_0^∞ \frac{E[T_x^p] - E[T_x]^p}{g_x^p \left( \frac{(1 ± ϵ) x}{1 - ρ} \right)} dF(t). \quad (4.5)\]

We would like to apply (4.4) to the denominator, but the variables in the subscript and function argument do not match. To make them match, observe in (4.1) that \(g_x^p(t)\) is decreasing in \(x\). By Conditions 4.1 and 4.2, for all sufficiently large \(x\) and all \(t \in (0, x)\),
\[E[T_x] ≤ E[T_x] \left( \frac{1 ± ϵ x}{1 - ρ} \right),\]

so for sufficiently large \(x\), we may replace \(t\) with \(x\) in the subscript of the denominator in (4.5). Using this along with Lemma 4.9 and (4.4) gives
\[P\left\{ T_x > \left( \frac{1 ± ϵ x}{1 - ρ} \right) \right\} \]
\[≤ \int_0^∞ \frac{E[T_x] - E[T_x]^p}{g_x^p \left( \frac{(1 ± ϵ) x}{1 - ρ} \right)} dF(t) \]
\[≤ \frac{1}{Ω(x^p)} \int_0^x \left( \left( \frac{t}{1 - ρ} \right)^p + φ(t)^p \right) dF(t) \]
\[≤ O(x^{-p}) \int_0^x φ(t)^p dF(t). \]

We continue the computation by integrating by parts and applying Lemma 2.2:
\[P\left\{ T_x > \left( \frac{1 ± ϵ x}{1 - ρ} \right) \right\} \]
\[≤ O(x^{-p}) - O(x^{-p}) \int_x^∞ φ(t)^p dF(t) \]
\[= O(x^{-p}) - O(x^{-p}) \left( φ(x^p) - O(1) \int_x^∞ φ(t)^p dF(t) \right) \]
\[≤ O(x^{-p}) + O(x^{-p}) \int_x^∞ φ(t)^p dF(t) \]
\[= O(x^{-p}) + O(x^{-p}) \int_x^∞ φ(t)^p dF(t) \]
\[= O(x^{-p}) + φ(1) F(x). \]

Lemma 2.2 and the fact that \(p > β > α\) imply that this is \(φ(F(x))\), so Condition 4.3(ii) holds.

Finally, the proof of our main result combines all of the pieces outlined in this section.

Proof of Theorem 3.3. Conditions 4.1–4.3 have been proven above and the theorem now follows from Proposition 4.4. \(\square\)

The bulk of the remainder of the paper is devoted to proving Lemmas 4.6 and 4.7, which give bounds on moments of size-conditional waiting and residence times. Our proofs of these lemmas rely on
detailed analysis of fractional moments of busy periods (Section 5) and on new general results about SOAP-policies (Section 6).

5 FRACTIONAL MOMENTS OF BUSY PERIODS
A key component of our proof of Theorem 3.3 is an analysis of the fractional moments of an M/G/1 queue. We write $B$ for the length of a busy period and $B_U$ for the length of a busy period with initial work $U$. Here, and throughout the paper, we denote the Laplace-Stieltjes transform (LST) of a random variable $V$ by

$$\tilde{V}(s) = E[\exp(-sV)].$$

We shall also encounter the excess $\mathcal{E}V$ of a random variable. It has distribution $\int_0^\infty P(V>y)dy$, furthermore, its LST is

$$\tilde{\mathcal{E}V}(s) = \frac{1 - \tilde{V}(s)}{sE[V]}.$$  (5.1)

Letting

$$\sigma(s) = s + \lambda(1 - \tilde{B}(s)),$$

we can write the LSTs of $B$ and $B_U$ as

$$\tilde{B}(s) = \tilde{X}(\sigma(s)),$$
$$\tilde{B_U}(s) = \tilde{U}(\sigma(s)).$$  (5.3)

Although the expression for $\tilde{B}(s)$ is recursive, it suffices for extracting moments.

Let $D$ be the derivative operator.

**Lemma 5.1.** The derivative of $\sigma(s)$ satisfies

$$D\sigma(s) = \frac{1}{1 - \lambda(-D)\tilde{X}(\sigma(s))}.$$  (5.4)

**Proof.** Differentiating (5.2) yields

$$D\sigma(s) = 1 - \lambda D\sigma(s) \cdot D\tilde{X}(\sigma(s)),$$

which rearranges to the desired equation. \hfill \Box

**Lemma 5.2.** For all $n \in \mathbb{Z}_+$,

$$(-D)^n\tilde{B_U}(s) = \sum_{i=1}^l d_i (D\sigma(s))^{a_i} (-D)^{b_i} \tilde{U}(\sigma(s)) \prod_{j=1}^k \lambda(-D)^c_{ij} \tilde{X}(\sigma(s)),$$

where $l, j_i, a_i, b_i, c_{ij}, d_i \in \mathbb{Z}_+$ are constants, independent of the system parameters $\lambda$ and $X$, satisfying

- $a_i, b_i \geq 1$ for all $i$,
- $c_{ij} \geq 2$ for all $i, j$,
- $b_i + \sum_{j=1}^k (c_{ij} - 1) = n$ for all $i$,
- $b_1 > \ldots > b_n$,
- $a_1 = b_1 = n$,
- $d_i = 1$,
- $j_1 = 0$.

**Proof.** See Appendix A.

As an immediate consequence, we have the following.

**Corollary 5.3.** For all $n \in \mathbb{Z}_+$,

$$E[B^n_U] = \sum_{i=1}^l d_i E[U_i^{b_i}] \prod_{j=1}^k \lambda E[X^{c_{ij}}],$$

where $l, j_i, a_i, b_i, c_{ij}, d_i \in \mathbb{Z}_+$ are as in Lemma 5.2.

The main result of this subsection is that nearly the same formula works for fractional moments, though it gives an upper bound instead of an exact result. To bound $E[B^n_U]$ for $p = n - q$, $n \in \mathbb{Z}_+$, we start with the formula for $E[B^n_U]$, then decrease some of the exponents by $q$. Specifically, for each $i$, we decrease $a_i$ and one more exponent of our choice, either $b_i$ or one of the $c_{ij}$.

**Theorem 5.4.** Let $p = n - q > 0$ for $n \in \mathbb{Z}_+$ and $q \in (0, 1)$. Then for all choices of $\chi_{ij} \in \{0, 1\}$ such that $\sum_{j=1}^k \chi_{ij} = 1$ for all $i$, we have

$$E[B^p_U] \leq \sum_{i=1}^l d_i E[U_i^{b_i - q\chi_{ij}}] \prod_{j=1}^k \lambda E[X^{c_{ij} - q\chi_{ij}}],$$

where $l, j_i, a_i, b_i, c_{ij}, d_i \in \mathbb{Z}_+$ are as in Lemma 5.2.

**Proof.** See Appendix A.

Remark. Bansal et al. [4] also formulate a bound on fractional moments of $G/G/1$ busy periods, but their bound only characterizes the growth rate in the $\rho \to 1$ limit. Focusing on the $M/G/1$ setting, in which a recursive LST is known for busy periods, enables us to obtain a much sharper bound in Theorem 5.4, characterizing the coefficients of each $1/(1 - \rho)^k$ term.

6 SOAP BACKGROUND
Recall from Section 2 that a SOAP policy is one defined by a rank function $r : \mathbb{R}_+ \to \mathbb{R}$ mapping each job’s age, or attained service, to its rank. The scheduler always serves the job of minimum rank, so lower rank means higher priority.

In this section we give background on how to analyze the mean response time of SOAP policies. Sections 6.1 and 6.2 review the response time analysis in [23], adapting the notation slightly to suit our needs. These expressions are hard to work with directly, and the complexity grows when considering higher moments. As such, we introduce new concepts and results in Sections 6.3 and 6.4 which help simplify the analysis.

6.1 Core SOAP Concepts
All of the definitions in the remainder of this section are given in terms of a generic SOAP policy with rank function $r$. We make the following standard assumption on rank functions [23, Appendix B].

**Assumption 6.1.** The rank function $r$ is piecewise monotonic and piecewise differentiable.

The way [23] analyzes response time of SOAP policies is with the “tagged job” approach, following the journey of a specific job from arrival to departure. Suppose the tagged job has size $x$. One of their key insights is that to determine the tagged job’s response time, its current rank is less important than the worst rank it will attain in its remaining time in the system.
Characterizing Policies with Optimal Response Time Tails under Heavy-Tailed Job Sizes

Definition 6.2. The worst future rank of a job of size $x$ at age $a$, written $w_x(a)$, is

$$w_x(a) = \sup_{a \leq b < x} r(b).$$

The worst ever rank of a job of size $x$ is $w_x = w_x(0)$.

When the tagged job initially enters the system, there may be a number of other jobs already present. Any other job with rank $w_x$ or less is ‘relevant’ to the tagged job, meaning it will receive some amount of service during the tagged job’s time in the system.

Definition 6.3. The amount of $w$-relevant work a job has is the amount of service it needs to either finish or attain rank greater than $w$. Similarly, the amount of $w$-relevant work in a system is the total amount of $w$-relevant work of all jobs in the system.

To find the response time of the tagged job, we need to know the amount of $w_x$-relevant work it encounters upon arrival. Because the arrival process is Poisson, this means finding the steady-state distribution of the amount of $w_x$-relevant work in the system, for which we need the following definition.

Definition 6.4.
(i) The $k$th $w$-relevant age interval is $(b_k[w], c_k[w])$, where

$$b_0[w] = 0$$

$$c_0[w] = \inf\{a \geq 0 \mid r(a) > w\}$$

$$b_k[w] = \inf\{a > c_{k-1}[w] \mid r(a) \leq w\} \quad \text{for all } k \geq 1$$

$$c_k[w] = \inf\{a > b_k[w] \mid r(a) > w\} \quad \text{for all } k \geq 1.$$

Additionally, let $K[w]$ be the number of $w$-relevant age intervals, namely the maximum $k$ such that $b_k[w] < \infty$. It may be that $K[w] = \infty$.

(ii) The $k$th $w$-relevant job segment is

$$X_k[w] \overset{st}{=} \max\{0, \min\{X, c_k[w]\} - b_k[w]\}.$$

(iii) The $k$th $w$-relevant load is

$$\rho_k[w] = \lambda E[X_k[w]].$$

For convenience, we also define

$$\rho_x[w] = \sum_{k=0}^{K[w]} \rho_k[w].$$

The tagged job can also be delayed by jobs arriving after it. The following definition helps us quantify this delay.

Definition 6.5. The $w$-relevant busy period, written $B[w]$, is the length of an $M/G/1$ busy period with arrival rate $\lambda$ and job size $X_0[w]$. Similarly, the $w$-relevant busy period with initial work $U$, written $B_U[w]$, is the length of such a busy period with initial work $U$.

6.2 SOAP Response Time Analysis

To study the response time of SOAP policies, we introduce the following random variables.

Definition 6.6. The residence time of a job of size $x$, written $R_x$, is a random variable with transform

$$\widetilde{R}_x(s) = \exp\left(-\int_0^x (s + \lambda(1 - B[w_x(a)])\right) da).$$

Abusing notation slightly, we can write the residence time as an integral of busy periods:

$$R_x = \int_0^x B_{da}[w_x(a) -].$$

Definition 6.7. The rank-$w$ waiting time, written $Q[w]$, is a random variable that has the same distribution as a particular busy period:

$$Q[w] = \int_0^x B_U[w] [w-].$$

where $U[w]$ is the steady-state amount of $w$-relevant work, which is a random variable with transform $[23, Lemma 5.2]$

$$E[Q[w]] = \frac{1 - \rho_x[w] + \sum_{i=0}^{K[w]} \rho_i[w] E[X_i[w]](s)}{1 - \rho_0[w] E[X_0[w]](s)}.$$

Scully et al. [23, Theorem 5.4] show that for any SOAP policy, $T_x$ is the independent sum of waiting and residence times, namely $T_x = \int_0^x Q[w] + R_x$, which implies the following formula for mean response time.

Corollary 6.8 ([23, Theorem 5.5]). Under any SOAP policy,

$$E[Q[w]] = \frac{1}{2} \sum_{i=0}^{K[w]} E[X_i[w]^2] \left(1 - \rho_0[w] (1 - \rho_x[w]) \right).$$

$$E[R_x] = \int_0^x \frac{1}{1 - \rho_0[w] E[X_0[w]](s)} da,$$

$$E[T_x] = E[Q[w]] + E[R_x].$$

6.3 Stochastic Response Time Bounds

The next two lemmas, proven in Appendix B, bound the residence and waiting time in terms of busy periods. The main concept in their proofs is the observation that jobs with rank larger than $w$ will not be served before the $w$-relevant busy period ends.

Lemma 6.9. For any SOAP policy, the residence time of a job of size $x$ is stochastically bounded by

$$R_x \leq \int_0^x B_{da}[w_x(a)].$$

Lemma 6.10. For any SOAP policy, the rank-$w$ waiting time is stochastically bounded by

$$Q[w] \leq \int_0^x \frac{\rho_0[w](1 - \rho_x[w])}{1 - \rho_0[w] E[X_0[w]](s)} da,$$

where

$$\pi_0[w] = \frac{\rho_0[w](1 - \rho_x[w])}{1 - \rho_0[w]}$$

$$\pi_k[w] = \frac{\rho_k[w]}{1 - \rho_0[w]} \quad \text{for all } k \geq 1.$$

These lemmas allow us to express response time moments in terms of busy period moments, which can be further analyzed using Theorem 5.4.
6.4 Additional SOAP Bounds

The purpose of the next few definitions is to formalize Assumption 3.2. All of them relate to the worst rank for a job of size $x$.

Definition 6.11. The maximum relevant age of a job of size $x$ is, roughly speaking, the latest age at which another job can possibly outrank it:

$$ u_x = c_K[w_x] \{ w_x \} = \sup \{ a > 0 \mid r(a) \leq w_x \}. $$

The next two definitions are due to Scully et al. [24].

Definition 6.12. A hill age is an age $b$ such that $r(a) < r(b)$ for all ages $a < b$. An age that is not a hill age is called a valley age.

Definition 6.13. The previous and next hill ages of $x$ are, respectively,

$$ y_x = c_0[ w_x^- ] $$

$$ z_x = c_0[ w_x ]. $$

For any $x$ such that $y_x < z_x$, we call the interval $(y_x, z_x)$ a valley, and any interval that does not overlap with a valley is called a hill. Figure 6.1 illustrates hills and valleys, including previous and next hill ages.

The next definition is not specific to SOAP but, as we will soon see, can be helpful when analyzing the moments of a SOAP policy’s response time.

(i) The $a$-cutoff job segment is $X(a) = \min(X, a)$.

(ii) The $a$-cutoff load is $p(a) = \lambda E[X(a)]$.

The $y_x$- and $z_x$-cutoff job segments give us another way to write $X_0[ w_x^- ]$ and $X_0[ w_x ]$:

$$ X_0[ w_x^- ] = \min(X, y_x), $$

$$ X_0[ w_x ] = \min(X, z_x). $$

(6.1)

The following lemma follows immediately from Definitions 6.6 and 6.7, observing that $w$-relevant busy periods are stochastically increasing in $w$.

Lemma 6.15.

(i) $Q[w]$ is stochastically increasing in $w$.

(ii) $r_x$ is stochastically increasing in $x$.

Note that Lemma 6.15 completes Step 3 of the proof described in Section 4. In fact, the only part of the proof outlined in Section 4 that remains to prove is Step 2, specifically Lemmas 6.4 and 6.7. We prove these lemmas in Section 7 with the help of the useful results given in the remainder of this section.

The next lemmas follow from integration by parts.

Lemma 6.16. For any $p > 0$,

$$ E[X_k^w] = \int_{b_k[w]} z_k[w] p(t - b_k[w])^{p - 1} F(t) \, dt. $$

Lemma 6.17. For any $p > 0$,

$$ E[X(a)^p] = \int_{0}^{a} p t^{p - 1} F(t) \, dt. $$

Previous and next hill ages are also useful for bounding moments of $X_k[ w_x ]$ for $k \geq 1$, specifically by combining Lemma 6.16 with the following lemma.

Lemma 6.18. For all ranks $w$ and $k \geq 1$, if $x \in (b_k[w], c_k[w])$, then

$$ y_x \leq b_k[w] < x < c_k[w] \leq z_x. $$

Proof. By Definition 6.13, we have $x \in (y_x, z_x)$, where $y_x$ is the first age at which the rank function reaches rank $w_x$, and $z_x$ is the first age at which the rank function strictly exceeds $w_x$. Because $k \geq 1$, there must be some age $a \leq b_k[w]$ at which $r(a) > b_k[w]$, so $w_x > w$. But by Definition 6.4, a job’s rank is at most $w$ during $(b_k[w], c_k[w])$, so $y_x, z_x \notin (b_k[w], c_k[w])$. We therefore must have $y_x \leq b_k[w]$ and $z_x \geq c_k[w]$. $\square$

7 PROVING TAIL OPTIMALITY

Recall from Section 4 that the proof is complete once we prove Lemmas 6.4 and 6.7. This section restates these lemmas in a slightly more convenient way (7.3-7.5) and provides the last of the necessary tools for the main proof. All lemmas in this section are proven in Appendix C.

Many of the statements in this section require similar preconditions on a parameter $p$. For convenience, we name these conditions $\Phi(p)$ and $\Psi(p)$:

$$ \Phi(p) \iff \frac{\zeta - \frac{1}{\eta}}{\frac{a - 1}{p}} < \frac{\alpha - 1}{p} \quad \text{or} \quad p \leq 0, $$

$$ \Psi(p) \iff 1 - \frac{\zeta}{\frac{a - 1}{p}} < \frac{\alpha - 1}{p} \quad \text{or} \quad p \leq 0. $$

For all $p \geq q$, we have\(^{10}\)

$$ \Phi(p) \Rightarrow \Psi(p), \quad \Phi(p) \Rightarrow \Psi(q), \quad \Psi(p) \Rightarrow \Psi(q). \quad (7.1) $$

In the proofs of Lemmas 7.3–7.5 we apply Theorem 5.4 in the case that the job sizes (including the initial work) are $w_x$-relevant job segments. The right hand side of the equation then contains moments of $w_x$-relevant job segments, which we bound in the next two lemmas.

\(^{10}\)The $\Phi(p) \Rightarrow \Psi(p)$ implication follows from $\zeta \leq \eta$ and the fact that $\Psi(p)$ is vacuously true for $\frac{\zeta}{\frac{a - 1}{p}} \leq 1$. 
Characterizing Policies with Optimal Response Time Tails under Heavy-Tailed Job Sizes

**Lemma 7.1.** For all $p > 0$ satisfying $\Psi(p)$, in the $x \to \infty$ limit,

$$E\{X_1[w_x]^{p+1}\} = \delta(x^p).$$

**Lemma 7.2.** For all $p > 0$ satisfying $\Phi(p)$, in the $x \to \infty$ limit,

$$\sum_{k=1}^{K} E\{X_k[w_x]^{p+1}\} = \delta(x^p).$$

Finally, we present the lemmas that complete the argument of Section 4. Their proofs use the busy period and SOAP analysis from Sections 5 and 6.

**Lemma 7.3.** For all $p > 0$ satisfying $\Psi(p)$, in the $x \to \infty$ limit,

$$E\{Q[w_x]^p\} \leq \delta(x^p).$$

**Lemma 7.4.** For all $p > 0$ satisfying $\Psi(p - 1)$, in the $x \to \infty$ limit,

$$E\{R_x^p\} \leq \left(\frac{x}{1 - \rho}\right)^p + \delta(x^p).$$

**Lemma 7.5.** If $\xi < 1$ or $\eta < \infty$, then in the $x \to \infty$ limit,

$$E\{R_x\} \geq \frac{x}{1 - \rho} - \delta(x).$$

8 DISCUSSION

Over the past decades, much effort has been given to the task of designing policies that maintain the optimal response time tail, i.e., a response time tail that is equally heavy as the tail of the job size distribution. While the analysis of individual policies has been successful in many cases, e.g., SRPT and FB, there are many important policies that have resisted analysis and, further, little is known about which scheduling mechanisms provably lead to tail optimality. In this paper, we provide general sufficient conditions on the type of prioritization that ensures tail optimality in policies that do not have access to job sizes. Our sufficient conditions enable the first results on tail-optimality for Gittins, RMLF, SERPT, and FB with limited preemption.

Although our sufficient conditions define a broad class of tail-optimal policies, it must be stressed that they are not necessary. For instance, Processor Sharing (PS), which is known to be tail-optimal, does not use job sizes and does not satisfy our sufficient conditions since it is not a SOAP policy. Thus, it is important to continue to develop both necessary and sufficient conditions for tail optimality. An interesting open question is to identify sufficient conditions that unify the results in [18] for size-based policies with the results in this paper on policies that do not have access to job size information. Additionally, the only necessary condition known for tail optimality is given by [26], which proves that all tail-optimal policies must “remain stable when faced with the arrival of a job with infinite size.” It is not known if this condition is also sufficient.

Another interesting research topic is to weaken the goal and, instead of looking to characterize policies that are tail-optimal, characterize classes of policies with near-optimal response time tails. It is known that the orders of the job size and response time tails can differ by any number $\gamma \in (0, 1] [8, 15]$, and so a natural question is: what forms of prioritization achieve these intermediate response time tails?

Finally, it is also worth considering tail optimality among light-tailed job size distributions. Are there sufficient conditions on prioritization that ensure tail optimality in the light-tailed setting? The results of [26] highlight that if a policy is tail-optimal under heavy-tailed job sizes it cannot be tail-optimal under light-tailed job sizes, and thus it is clear that the sufficient conditions must change. However, little is known about the general class of policies that are (nearly) tail-optimal under light-tailed job sizes. More broadly, an important open question first posed in [15] is: what are sufficient conditions that ensure a policy is near-optimal for the response time tail under both heavy- and light-tailed job size distributions?

REFERENCES

A PROOFS FOR SECTION 5

Recall that, for any nonnegative random variable \( V \) and \( n \in \mathbb{Z}_+ \),
\[
(-D)^n \tilde{V}(s) = E[V^n \exp(-sV)],
\] (A.1)
so in particular \( E[V^n] = (-D)^n \tilde{V}(0) \). Furthermore, if \( p = n - q > 0 \) for \( q \in (0, 1) \),
\[
E[V^p] = \int_0^\infty t^{n-q} \exp(-st) \, dt \, dP[V \leq t]
= \int_{t=0}^{\infty} \frac{\Gamma(q)}{\Gamma(q)} \int_{s=0}^{\infty} s^q \exp(-st) \, ds \, dP[V \leq t]
= \int_{t=0}^{\infty} \frac{1}{s^{1-q} \Gamma(q)} \int_{s=0}^{\infty} s^q \exp(-st) \, ds \, dP[V \leq t]
= \int_0^\infty \frac{1}{s^{1-q} \Gamma(q)} (-D)^n \tilde{V}(s) \, ds.
\] (A.2)

**Lemma 5.2.** For all \( n \in \mathbb{Z}_+ \),
\[
(-D)^n B_t(s) = \sum_{i=1}^l a_i (-D)^b_i \tilde{U}(s) \prod_{j=1}^l \lambda(-D)^b_j \tilde{X}(s),
\]
where \( l, j, a_i, b_i, c_{ij}, d_i \in \mathbb{Z}_+ \) are constants, independent of the system parameters \( \lambda \) and \( X \), satisfying
\[
a_i, b_i \geq 1 \quad \text{for all } i,
\]
\[
c_{ij} \geq 2 \quad \text{for all } i, j,
\]
\[
b_i + \sum_{j=1}^k (c_{ij} - 1) = n \quad \text{for all } i,
\]
\[
b_1 > \ldots > b_n,
\]
\[
a_1 = b_1 = n,
\]
\[
d_i = 1,
\]
\[
j_i = 0.
\]

**Proof.** We proceed by induction on \( n \). The base case of \( n = 0 \) is immediate by (5.3), so we turn to the inductive step. By relabeling, we can have \( a_1 > \ldots > a_n \) without loss of generality. We address the constraint on the \( i = 1 \) constants at the end of the proof.

For \( a, b, c_j \in \mathbb{Z}_+ \), let
\[
\tau_{a,b,c_1,...,c_j}(s) = (-D\sigma(s))^a \cdot (-D)^b \tilde{U}(\sigma(s)) \prod_{j=1}^f \lambda(-D)^b \tilde{X}(\sigma(s)).
\]
We abbreviate \( c = (c_1, \ldots, c_j) \). Call \( b + \sum_{j=1}^f (c_j - 1) \) the degree of \( \tau_{a,b,c}(s) \). For the inductive step, it suffices to show that the derivative of a term with degree \( n \) is a sum of terms with degree \( n + 1 \). Using

**Lemma 5.1.** We compute\(^1\)
\[
-D\tau_{a,b,c}(s) = \tau_{a+1,b+1,c}(s) + a\tau_{a+2,b,c_1,...,c_j}(s)
+ \sum_{j=1}^f \tau_{a+1,b,c_1,...,c_1+1,...,c_j}(s),
\] (A.3)
in which each term has degree \( n + 1 \), as desired.

We now address the constraint on the \( i = 1 \) term, again by induction on \( n \). The base case of \( n = 0 \) is immediate by (5.3), and the inductive step follows from plugging \( a = b = n \) into (A.3). □

**Lemma A.1.** Let \( p = m - q > 0 \) for \( m \in \mathbb{Z}_+ \) and \( q \in (0, 1) \). Then for any nonnegative random variable \( V \), we have
\[
\int_{s=0}^{\infty} \frac{1}{s^{1-q} \Gamma(q)} (-D)^m \tilde{V}(\sigma(s)) \cdot D\sigma(s) \, ds \leq \frac{E[V^p]}{(1 - \rho)^{1-q}}.
\]
**Proof.** We first show that for all \( s > 0 \),
\[
\frac{\sigma(s)}{s} \leq \frac{1}{1 - \rho}.
\] (A.4)
By (5.2),
\[
\sigma(s) = s + \lambda (1 - \tilde{X}(\sigma(s)))
= s + \lambda \int_{X=0}^{\infty} (1 - \exp(-X\sigma(s))) \, dP[X \leq x]
\leq s + \lambda E[X] \sigma(s),
\]
which implies (A.4). Using the above and making a change of variable \( \sigma = \sigma(s) \) yields
\[
\int_{s=0}^{\infty} \frac{1}{s^{1-q} \Gamma(q)} (-D)^m \tilde{V}(\sigma(s)) \cdot D\sigma(s) \, ds
\leq \frac{1}{(1 - \rho)^{1-q}} \int_{s=0}^{\infty} \frac{\sigma(s)}{s^{1-q} \Gamma(q)} (-D)^m \tilde{V}(\sigma(s)) \cdot D\sigma(s) \, ds
\leq \frac{1}{(1 - \rho)^{1-q}} \int_{s=0}^{\infty} \frac{E[V^p]}{(1 - \rho)^{1-q}} \, ds
\leq E[V^p],
\]
where the last equality follows from (A.2). □

**Proof of Theorem 5.4.** Let \( V \) be a nonnegative random variable. By (A.1), for all \( m \in \mathbb{Z}_+ \) and \( s > 0 \),
\[
(-D)^m \tilde{V}(\sigma(s)) \leq (-D)^m \tilde{V}(0) = E[V^m],
\] (A.5)
which when applied to (A.4) implies
\[
D\sigma(s) \leq \frac{1}{1 - \rho}.
\] (A.6)
\(^1\)Two clarifications about the list notation below. First, in the second term on the right-hand side, we append \( c \) with an extra 2. Second, for each \( j \), in the \( j \)th summand of the third term on the right-hand side, we increase the \( j \)th element of \( c \) by 1.
Combining (A.6) and Lemma 5.2 yields

\[ E[P^i_{\rho}] = \int_0^\infty \frac{1}{s^{1-\eta}} (-D)^n \tilde{B}_U(s) \, ds \]

\[ = \int_0^\infty \frac{1}{s^{1-\eta}} \left( \sum_{i=1}^l d_i (D \sigma(s))^a \cdot (-D)^b \tilde{U}(\sigma(s)) \right) \cdot \tilde{X}(\sigma(s)) \, ds \]

\[ \leq \sum_{i=1}^l \frac{d_i}{(1-\rho)^{\mu_i-1}} \int_0^\infty \frac{1}{s^{1-\eta}} (-D)^b \tilde{U}(\sigma(s)) \cdot \tilde{X}(\sigma(s)) \cdot D \sigma(s) \, ds \]

This gives the desired bound for the ith summand in (A.7). The case where \( \mu_j = 1 \) for some \( j \geq 1 \) is very similar, except we apply Lemma A.1 with \( V = X \) and \( m = \epsilon_{ij} \). \( \square \)

\[ \int_0^\infty \frac{1}{s^{1-\eta}} (-D)^b \tilde{U}(\sigma(s)) \cdot \tilde{X}(\sigma(s)) \cdot D \sigma(s) \, ds \]

\[ \leq \int_0^\infty \frac{1}{s^{1-\eta}} (-D)^b \tilde{U}(\sigma(s)) \cdot D \sigma(s) \, ds \]

\[ \leq E[U^b] \sum_{j=1}^l \lambda \tilde{E}[X^{\epsilon_{ij}}] \]

\[ \leq \frac{E[U^b]}{(1-\rho)^{-q}} \sum_{j=1}^l \lambda \tilde{E}[X^{\epsilon_{ij}}] \]

which gives the desired bound for the ith summand in (A.7). The case where \( \mu_j = 1 \) for some \( j \geq 1 \) is very similar, except we apply Lemma A.1 with \( V = X \) and \( m = \epsilon_{ij} \). \( \square \)

Remark. Note that one might hope to get a simpler expression for \((-D)^n \tilde{B}_U(s) = (-D)^n \tilde{U}(\sigma(s)) \) by applying the following compact form of Faà di Bruno’s formula for derivatives of composite functions [13]:

\[ \frac{d^n}{ds^n} \tilde{U}(\sigma(s)) = \sum_{k=1}^n \frac{d^k}{dy^k} B_{n,k}(\sigma(s), \sigma(s) \ldots, \sigma(s)) \bigg|_{y=\sigma(s)} \]

where the partial or incomplete exponential Bell polynomials \( B_{n,k} \) are given by

\[ B_{n,k}(x_1, \ldots, x_{n-k+1}) = \sum_{j_1! \cdots j_{n-k+1}!} \frac{n!}{j_1! \cdots j_{n-k+1}!} (\frac{x_1}{j_1!} \cdots (\frac{x_{n-k+1}}{(n-k+1)!}))^{j_{n-k+1}} \]

where the sum is taken over all nonnegative integers \( (j_1, \ldots, j_{n-k+1}) \)

B. PROOFS FOR SECTION 6

Lemma 6.9. For any SOAP policy, the residence time of a job of size \( x \) is stochastically bounded by

\[ R_x \leq \text{st} \int_0^x B_{d\alpha}[w_x(a)-] \]

Proof. By Definition 6.6,

\[ R_x = \text{st} \int_0^x B_{d\alpha}[w_x(a)-] \]

It is clear from Definition 6.5 that \( B_U[w] \) is stochastically increasing in \( w \) for any \( U \). Definition 6.2 implies \( w_x \geq w(x) \) for all \( a \geq 0 \), so

\[ R_x \leq \text{st} \int_0^x B_{d\alpha}[w_x] = \text{st} B_x[w_x] \]

Lemma 6.10. For any SOAP policy, the rank-\( w \) waiting time is stochastically bounded by

\[ Q[w] \leq \text{st} \begin{cases} E B_{X_1}[w][w] & \text{w.p. } \pi_0[w], \\ \vdots & \\ E B_{X_k}[w][w] & \text{w.p. } \pi_k[w], \\ 0 & \text{w.p. } 1 - \rho_2[w], \end{cases} \]

where

\[ \pi_0[w] = \frac{\rho_0[w]}{1 - \rho_2[w]} \]

\[ \pi_k[w] = \frac{\rho_k[w]}{1 - \rho_0[w]} \] for all \( k \geq 1 \).

Proof. Following the approach of [23, Section 5], one can think of \( Q[w] \) as defined by the following process. A job \( J \) with initial rank \( r \) arrives at a random time. Because the system uses FCFS tiebreaking between jobs of the same rank, job \( J \) is first served when

- all jobs that arrived before \( J \) either complete or have rank strictly greater than \( r \), and
- all jobs that arrived after \( J \) either complete or have rank greater than or equal to \( r \).
Then $Q[w]$ is the amount of time from $J$'s arrival to its first service. Define $Q'[w]$ in the same way as $Q[w]$ but in a system that breaks rank ties by prioritizing all other jobs over $J$. Clearly, $Q[w] \leq Q'[w]$.

But we can succinctly describe $Q'[w]$: it is either 0 or the excess of a $w$-relevant busy period with some amount of initial work. Specifically, the initial work is a $k$th $w$-relevant job segment for some $k \geq 0$. Thus, letting $\pi_k[w]$ be the steady-state probability that the system is in a $w$-relevant busy period started by a $k$th $w$-relevant segment, we have

$$Q'[w] = \begin{cases} E B_{X_k[w]}[w] & \text{w.p. } \pi_0[w], \\ \vdots & \\ 0 & \text{w.p. } 1 - \rho_k[w]. \end{cases}$$

All that remains is to compute the probabilities $\pi_k[w]$. For $k \geq 1$, each job's $k$th $w$-relevant segment starts a $w$-relevant busy period with expected length $\mathbb{E}[X_k[w]]/(1 - \rho_k[w])$, and jobs arrive at rate $\lambda$, so for $k \geq 1$, $\pi_k = \frac{\rho_k[w]}{1 - \rho_k[w]}$.

The $k = 0$ case is similar, except that a job's 0th $w$-relevant segment only starts a $w$-relevant busy period if the system has no $w$-relevant work. Thus, the arrival rate of jobs whose 0th $w$-relevant segment starts a $w$-relevant busy period is $\lambda(1 - \rho_0[w])$, so $\pi_0 = \frac{\rho_0[w](1 - \rho_2[w])}{1 - \rho_0[w]}$. $\Box$

### C PROOFS FOR SECTION 7

**Lemma 7.1.** For all $p > 0$ satisfying $\Psi(p)$, in the $x \to \infty$ limit, $\mathbb{E}[X_0[w_x]p^{+1}] = \hat{d}(x^p)$.

**Proof.** By (6.1) and Lemma 6.17,

$$\mathbb{E}[X_0[w_x]p^{+1}] = \mathbb{E}[X(z_x)p^{+1}] = \int_0^{z_x} (p + 1)t^p \tilde{F}(t) \, dt.$$ 

Hence for $x \to \infty$,

$$\mathbb{E}[X_0[w_x]p^{+1}] = \int_0^\infty \mathbb{E}[t^p] \tilde{F}(t) \, dt.$$ 

Then for all $k \geq 0$, we compute

$$\mathbb{E}[X_k[w_x]p^{+1}] = \int_0^\infty \mathbb{E}[t^p] \tilde{F}(t) \, dt.$$ 

**Lemma 7.2.** For all $p > 0$ satisfying $\Phi(p)$, in the $x \to \infty$ limit,

$$\sum_{k=1}^{K[w_x]} \mathbb{E}[X_k[w_x]p^{+1}] = \hat{d}(x^p).$$ 

**Proof.** By Lemmas 6.16 and 6.18 and Assumption 3.2,

$$\sum_{k=1}^{K[w_x]} \mathbb{E}[X_k[w_x]p^{+1}] = \sum_{k=1}^{K[w_x]} \int_{w_x}^\infty \mathbb{E}[b_k(w_x)(p + 1)t^p \tilde{F}(t) \, dt = \sum_{k=1}^{K[w_x]} \int_{w_x}^\infty \mathbb{E}[b_k(w_x)(p + 1)t^p \tilde{F}(t) \, dt.$$ 

Hence for $x \to \infty$,

$$\sum_{k=1}^{K[w_x]} \mathbb{E}[X_k[w_x]p^{+1}] = \int_0^\infty \mathbb{E}[t^p] \tilde{F}(t) \, dt = \mathbb{E}[t^p] \tilde{F}(t) \, dt.$$ 

**Lemma 7.3.** For all $p > 0$ satisfying $\Phi(p)$, in the $x \to \infty$ limit, $\mathbb{E}[Q[w_x]p] \leq \hat{d}(x^p)$.

**Proof.** By Lemma 6.10,

$$\mathbb{E}[Q[w_x]p] \leq \sum_{k=1}^{K[w_x]} \mathbb{E}[X_k[w_x]p^{+1}] = \sum_{k=1}^{K[w_x]} \mathbb{E}[b_k(w_x)(p + 1)t^p \tilde{F}(t) \, dt = \sum_{k=1}^{K[w_x]} \mathbb{E}[b_k(w_x)(p + 1)t^p \tilde{F}(t) \, dt.$$ 

Then for all $k \geq 0$, we compute

$$\mathbb{E}[X_k[w_x]p^{+1}] = \mathbb{E}[b_k(w_x)(p + 1)t^p \tilde{F}(t) \, dt.$$ 

Bounding the right hand side of (C.3) provides a bound for fractional busy period moments. We now apply Theorem 5.4 to the $(p + 1)$th moment above, letting $p + 1 = n - q$ for $n \in \mathbb{Z}_+$ and $q \in (0, 1)$. We choose $x_0 = 1$ for all $i$ such that $b_i \geq 2$ and $x_{11} = 1$ for all other $i$. $\Box$

This choice ensures that $b_i - qx_0 \geq 1$, $c_{ij} - qx_{ij} > 1$, which will allow the use of Lemmas 7.1 and 7.2 later in the proof.

---

12The possibility of a job completing before reaching its $k$th $w$-relevant segment is not a problem: this corresponds to the outcome $X_k[w] = 0$, in which case we think of the segment as starting a $w$-relevant busy period of length 0.

13This choice requires checking that $b_i \geq 1$ for all $i$ such that $b_i = 1$, which holds by (C.5) and the fact that $n \geq 2$. 

---

Ziv Scully, Lucas van Kreveld, Onno Boxtma, Jan-Pieter Dorsman, and Adam Wierman
Applying Theorem 5.4 to (C.3) yields, for \( x \to \infty \),
\[
\pi_k[w_x] \cdot E[EB_{X_k}[w_x][w_x]^P] \\
\leq O(1) \cdot \sum_{i=1}^{\infty} d_i E[X_k[w_x]^{b_i-q\chi_{i0}}] \prod_{j=1}^{b_i} E[X_0[w_x]^{c_{ij}-q\chi_{ij}}] \\
= O(1) \cdot \sum_{i=1}^{\infty} E[X_k[w_x]^{b_i-q\chi_{i0}}] \prod_{j=1}^{b_i} E[X_0[w_x]^{c_{ij}-q\chi_{ij}}].
\]
(C.4)

Recall from Lemma 5.2 that
\[
b_i - q\chi_{i0} + \sum_{j=1}^{b_i} (c_{ij} - q\chi_{ij}) = n - q = p + 1.
\]
(C.5)

This means for all \( i \) and \( j \), we have \( c_{ij} - q\chi_{ij} - 1 \leq p \), so \( \Psi(c_{ij} - q\chi_{ij} - 1) \) holds by (7.1). Returning to (C.4), applying Lemma 7.1 and (C.5) gives us
\[
\pi_k[w_x] \cdot E[EB_{X_k}[w_x][w_x]^P] \\
\leq \sum_{i=1}^{\infty} \prod_{j=1}^{b_i} \delta(x^{c_{ij}-q\chi_{ij}})^{-1}) \\
= \sum_{i=1}^{\infty} E[X_k[w_x]^{b_i-q\chi_{i0}}] \max\{O(1), \delta(x^{\sum_{j=1}^{b_i} (c_{ij} - q\chi_{ij})})\} \\
= \sum_{i=1}^{\infty} E[X_k[w_x]^{b_i-q\chi_{i0}}] \max\{O(1), \delta(x^{p-(b_i-q\chi_{i0})})\},
\]
(C.6)

where the \( O(1) \) covers the \( J_i = 0 \) case, in which the product is empty.

We now return to computing (C.2), substituting in (C.6) and interchanging the order of summation:
\[
E[Q[w_x]^P] \leq \sum_{i=1}^{\infty} \max\{O(1), \delta(x^{p-(b_i-q\chi_{i0})})\} \sum_{k=0}^{K[w_x]} E[X_k[w_x]^{b_i-q\chi_{i0}}] \\
= \sum_{k=0}^{K[w_x]} E[X_k[w_x]] \\
= \sum_{k=0}^{K[w_x]} \sum_{x=0}^{\infty} X_k[w_x] \leq E[X] = O(1).
\]

Combining this with Lemmas 7.1 and 7.2 gives us
\[
\max\{O(1), \delta(x^{p+1-(b_i-q\chi_{i0})})\} \sum_{k=0}^{K[w_x]} E[X_k[w_x]^{b_i-q\chi_{i0}}] \\
\leq \max\{O(1), \delta(x^{p+1-(b_i-q\chi_{i0})})\} \cdot \max\{O(1), \delta(x^{b_i-q\chi_{i0} - 1})\} \\
= \delta(x^p).
\]

Lemma 7.4. For all \( p > 0 \) satisfying \( \Psi(p - 1) \), in the \( x \to \infty \) limit,
\[
E[R_x^p] \leq \left( \frac{x}{1 - \rho} \right)^p + \delta(x^p).
\]

Proof. Let \( p = n - q \) for \( n \in \mathbb{Z}_+ \) and \( q \in (0, 1) \). We again apply Theorem 5.4, choosing \( \chi_{i0} = 1 \) for all \( i \). By Lemma 6.9,
\[
E[R_x^p] \leq E[R_x^p[w_x]] \\
\leq \left( \frac{x}{1 - \rho_0[w_x]} \right)^p + \sum_{i=1}^{\infty} d_i \left( \frac{x^{-b_i-q}}{1 - \rho_0[w_x]} \right)^q \prod_{j=1}^{b_i} \lambda E[X_0[w_x]^{c_{ij}}].
\]

Recall from Lemma 5.2 that
\[
b_i - q + \sum_{j=1}^{b_i} (c_{ij} - 1) = n - q = p.
\]
This means for all \( i \) and \( j \), we have \( c_{ij} - 1 \leq p - b_i \leq p - 1 \), so \( \Psi(c_{ij} - 1) \) holds by (7.1). We can therefore apply Lemma 7.1, which yields
\[
\sum_{i=1}^{\infty} d_i \left( \frac{x^{-b_i-q}}{1 - \rho_0[w_x]} \right)^q \prod_{j=1}^{b_i} \lambda E[X_0[w_x]^{c_{ij}}] \\
= \sum_{i=1}^{\infty} O(x^{b_i-q}) \prod_{j=1}^{b_i} \delta(x^{c_{ij}-1}) \\
= \sum_{i=1}^{\infty} \delta(x^{b_i-q+\sum_{j=1}^{b_i} (c_{ij}-1)}) \\
= \delta(x^p).
\]

Lemma 7.5. If \( \zeta < 1 \) or \( \eta < \infty \), then in the \( x \to \infty \) limit,
\[
E[R_x] \geq \frac{x}{1 - \rho} - \delta(x).
\]

Proof. We consider the \( \zeta < 1 \) and \( \eta < \infty \) cases separately.

Case 1: \( \zeta < 1 \). Definitions 6.4 and 6.13 imply \( w_x(a) = w_x \) for all \( a \in [0, y_x) \). From this, (6.1), Corollary 6.8, and Assumption 3.2, we compute
\[
E[R_x] = \int_0^x \frac{1}{1 - \rho_0[w_x(a)-]} \, da \\
\geq \int_0^{y_x} \frac{1}{1 - \rho_0[w_x(a)-]} \, da \\
= \frac{y_x}{1 - \rho_0[w_x]} \\
\geq \frac{x - O(x^\zeta)}{1 - \rho(x - O(x^\zeta))} \\
= \frac{x}{1 - \rho(x^\zeta)} - \delta(x).
\]

For any \( \rho' \in (0, \rho) \), we have
\[
\frac{1}{1 - \rho'} \geq \frac{1}{1 - \rho} \cdot \frac{1 + \rho \rho'}{1 - \rho' + \rho'} \geq \frac{1}{1 - \rho} - \frac{\rho - \rho'}{(1 - \rho)^2}.
\]
Applying this to Corollary 6.8 yields
\[ \rho - \rho(\Omega(x)) = \int_0^\infty F(t) \, dt - \int_0^\infty \Omega(x) \, dt = \int_0^\infty \Omega(x) \, dt = O(t^{-\alpha}) \]
This indeed holds by Lemma 6.17:
\[ = O(\omega^{-\alpha + 1}) = \delta(1). \]

Case 2: \( \eta < \infty \). A job’s worst future rank \( w_x(a) \) is decreasing in \( a \) by Definition 6.2, so for all \( a \in [0, x) \),
\[ w_x(a) \geq w_x(x-) = r(x-). \]
Applying this to Corollary 6.8 yields
\[ E[R_x] = \int_0^x \frac{1}{1 - \rho_0[w_x(a)-]} \, da \geq \frac{x}{1 - \rho_0[r(x-)]}. \]
By (C.7) with \( \rho' = \rho_0[r(x-)] \), it suffices to show \( \rho - \rho_0[r(x-)] = \delta(1) \).

Let \( f(\cdot) \) be a strictly increasing function such that for sufficiently large \( t \),
\[ u_t \leq f(t) \leq 2u_t. \] (C.8)
Definition 6.4 tells us that for all ages \( a > f(t) \), we have \( r(a) > u_t \).
But by Definitions 6.2 and 6.4, we have \( r(x-) \leq r(c_0[r(x-)]) = w_x(c_0[r(x-)]) \)
so it must be that \( x \leq f(c_0[r(x-)]) \). Because \( f(\cdot) \) is strictly increasing, it is invertible, so Assumption 3.8 and (C.8) imply
\[ c_0[r(x-)] \geq f^{-1}(x) = \Omega(x^{1/\eta}). \]
Combining this with (6.1) and Lemma 6.17, we compute, similarly to the previous case,
\[ \rho - \rho_0[r(x-)] = \rho - \rho(\Omega(x^{1/\eta})) = \int_0^\infty O(t^{-\alpha}) \, dt = O(x^{-(\alpha - 1)/\eta}) = \delta(1). \]

\section{GENERALIZATION TO SOAP BUBBLE POLICIES}
In this appendix we generalize our main results, Theorems 3.1 and 3.3, to SOAP Bubble policies, which are a superset of SOAP policies that is introduced in [22]. To review (see Section 3.4), a SOAP Bubble policy has lower and upper rank functions
\[ r^-, r^+: \mathbb{R}_+ \rightarrow \mathbb{R}. \]
A SOAP Bubble policy works like a SOAP policy, except each job \( j \) can have a different rank function \( r_j \). Each job’s rank function may be set arbitrarily, provided it remains within the “bubble” between the lower and upper rank functions, meaning for all jobs \( j \) and ages \( a \),
\[ r^-(a) \leq r_j(a) \leq r^+(a). \]
One can view ordinary SOAP policies as the special case with \( r^- = r = r^+ \).

To upper bound the response time of a SOAP bubble policy, one can essentially replicate the analysis of SOAP policies, but replacing each use of \( r \) with either \( r^- \) or \( r^+ \) as appropriate. The intuition is that a tagged job has maximal response time if it follows \( r^+ \) while every other job follows \( r^- \). Specifically,
- when defining worst future rank (Definition 6.2), replace \( r \) with \( r^+ \);
- when defining \( w \)-relevant work, intervals, segments, and load (Definitions 6.3 and 6.4), replace \( r \) with \( r^- \).

For details, see [22].

To generalize Theorems 3.1 and 3.3, we begin by defining some new notation. Let \( r^- = \sup_{0 \leq b < x} r^-(b) \):
\[ w_x = \sup_{0 \leq b < x} r^+(b), \]
\[ y_x = c_0[w_x], \]
\[ z_x = c_0[w_x], \]
\[ u_x = \sup_{x \geq y_x} \sup_{x \geq z_x} \\cdots \sup_{x \geq z_x}. \]
Throughout our proofs, we can simply replace \( u_x \) with \( u_x \), but \( y_x \) and \( z_x \) are more subtle.
- The main use of \( y_x \) and \( z_x \) is through Lemma 6.18, which is used in Lemma 7.2. The lemma statement now holds with \( y_x \) and \( z_x \).
- There is one more use of \( y_x \) in Lemma 7.5, and this one needs to be replaced with \( y_x \).
- There is one more use of \( z_x \) in Lemma 7.1, and this one needs to be replaced with \( z_x \).

This implies the following generalizations of Assumption 3.2 and Theorem 3.3. The only substantial change is that we need two versions of \( \zeta \) because there are two version of \( y_x \) and \( z_x \). This ends up breaking the \( \Phi(p) \Rightarrow \Psi(p) \) implication in (7.1), so we add some extra preconditions to our result.

\textbf{Assumption D.1.}
(i) There exists \( \zeta^- \in [0, \infty) \) such that \( z_x^- - y_x^- = O(x^{1/\eta}) \).
(ii) There exists \( \zeta^+ \in [\zeta^-, \infty) \) such that \( z_x^+ - y_x^+ = O(x^{1/\eta}) \).
(iii) There exists \( \eta^+ \in (1, \zeta^+) \) such that \( u_x = O(x^{\eta^+}) \).

\textbf{Theorem D.2.} Consider an \( M/G/1 \) queue whose job size distribution obeys Assumption 2.1 and a SOAP Bubble scheduling policy whose lower and upper rank functions obey Assumption D.1. If
\[ \zeta^- - \frac{1}{\eta^+} < \frac{\alpha - 1}{\beta}, \]
\[ 1 - \frac{1}{\zeta^+} < \frac{\alpha - 1}{\beta}, \]
and either \( \zeta^+ < 1 \) or \( \eta^+ < \infty \),
then the policy is tail-optimal, i.e., \( \lim_{x \to \infty} \frac{1}{F(x)} P\{T > \frac{x}{r^+} \} = 0 \).

One can obtain the following simplified condition in much the same way as done in Theorem 3.1.

\[ \text{Recall that } c_x[w] \text{ is defined using } r^- \]
Theorem D.3. Consider an $M/G/1$ queue whose job size distribution obeys Assumption 2.1 using a SOAP Bubble scheduling policy whose lower and upper rank functions obey

\[ r^-(a) = \Omega(a^\gamma), \]
\[ r^+(a) = O(a^{\delta}) \]

for some $\delta > \gamma > 0$. If

\[ \frac{\delta - \gamma}{\delta} < \frac{\alpha - 1}{\beta}, \]

then the policy is tail-optimal, i.e.,
\[ \lim_{x \to \infty} \frac{1}{F(x)} P\{T > \frac{x}{1-P}\} = 1. \]
